

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + Refrain from automated querying Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at http://books.google.com/

THE

NAVAL CONSTRUCTOR:

A VADE MECUM

OF

SHIP DESIGN FOR STUDENTS, NAVAL ARCHI-TECTS, SHIPBUILDERS AND OWNERS, MARINE SUPERINTENDENTS, ENGI-NEERS AND DRAUGHTSMEN.

BY

GEORGE SIMPSON,

MEMBER OF THE INSTITUTION OF NAVAL ARCHITECTS, ASSOC. MEMBER AMERICAN SOCIETY OF NAVAL ENGINEERS.

Third Edition, Revised and Enlarged.

NEW YORK.

PREFACE TO FIRST EDITION.

THIS HANDBOOK has been prepared with the object of supplying a ready reference for those engaged in the design, construction, or maintenance of ships, — such a work as should give simply and concisely, information on most of the points usually dealt with in the theory and practice of marine architecture, and in addition much that is new and original. Under the latter heading should be included the chapter on Design and many of the tables of standardized fitting details, etc.

The Freeboard tables have been explained and their application simplified by working out examples embracing the various types to which freeboards are assigned, including the modern shelter decker, for which rules

have recently been issued.

While it would have been possible to enlarge greatly on what the author has attempted, it has been deemed prudent at present to restrict somewhat the scope of the book, although at that, it will be found much more comprehensive in its character than existing works on naval architecture.

It has been the author's aim to eliminate all obsolete matter and antiquated data, and to bring the book right in line with present day requirements.

How nearly he has come to this ideal will be shown

by the reception accorded by the profession.

His thanks are especially due to Ernest H. Rigg, A. M. I. N. A., for valuable assistance in the preparation of the chapter on Freeboard, to Jas. A. Thomson, M. I. N. A., for aid in the reading of proofs, and to the publishers for their hearty co-operation.

GEORGE SIMPSON.

647 RICHMOND TERRACE, MARINER HARBOR, NEW YORK CITY, MAY, 1904.

PREFACE TO THIRD EDITION.

THE preceding editions of this handbook were received so favorably that it was decided to enlarge the third edition by the addition of further "unified" details such as made the earlier editions noteworthy. There has also been included much new matter dealing with ventilation and other subjects, while other portions of the book have been revised and brought up-to-date.

It is hoped that in its enlarged form "The Naval Constructor" will continue to occupy its present position as a daily book of reference for those engaged in the design, construction and maintenance of ships.

GEORGE SIMPSON.

17 Battery Place, New York City, 1st May, 1914.

CONTENTS.

Section I. — Ship Calculations.

Symbols — Algebraical Signs — Displacement — Simpson's First Rule - Multipliers for Subdivided Intervals - Proof of Simpson's Rule - Displacement Sections - Bottom Half-breadth - Displacement Table—Area of Water Plane—Tons per Inch Immersion—Coefficient—Immersion Passing from Salt to Fresh Water — Area of Midship Section — Coefficient 8 — Prismatic Coefficient — Centre of Buoyancy — Approximate Rule for Centre of Buoyancy - Centre of Buoyancy Longitudinally - Transverse Metacentre — B. M. — Moment of Inertia of Water Plane — Longitudinal Metacentre — Centre of Flotation — Approximate Rule for L.B.M. — Moment to Change Trim — Change of Trim — Moment to Alter Trim One Inch — Approximate Rule for M. — Alteration in Trim through shipping a small weight - Tchibyscheff's Sections for "Lucania" - Displacement Sheet by Tchibyscheff's Rule -- Centre of Buoyancy by Tchibyscheff's Rule --L.M.C. and Centre of Flotation by Tchibyscheff's Rule - Transverse Metacentres by Tchibyscheff's Rule - Effect of Form of Water Line on Position of Longitudinal Metacentre - Effect of Form of Water Line on Position of Transverse Metacentres — Explanation of Tables on Position of Metacentres - Stability Calculation by Tchibyscheff's Rule - Tchibyscheff's Sections for Stability Levers - Calculation of G.Z. by Tchibyscheff's Rule -Cross Curves of Stability—Stability Curves—Design—Block Coefficient—Relation Coefficient ε —Mid Area Coefficient β — Prismatic Coefficient — Area of L.W.L. Coefficient a — Inertia Coefficient "i" -- Centre of Gravity Coefficient "g" -- Bilge Diagonal Coefficient - Element Coefficient - Relation of the Coefficients to one another — Element Coefficients for various Types -Coefficients for Centre of Gravity -- Moment of Inertia of Waterline Coefficient - Sheer - Contour of Stern - Figureheads and Lacing Pieces — Rail Half-breadths — Load Line Half-breadths - Diagram of Bilge Diagonals - Diagram of L.W.L. Half-breadths -Body Plan of "Oceanic" - Designing the Bossing - Fairing the Bossing — Fairing the Oxter — Elements of Marine Engines — Engine Room Lengths—The Preparation of Specifications - Specification Headings - Freeboard - Length - Breadth -

Depth of Hold -- Coefficient of Fineness -- Moulded Depth --Freeboard — Vessels of Extreme Proportions — Breadth and Depth - Erections on Deck - Sheer - Round of Beam - Explanatory Notes on Application of Freeboard Tables — Additional Freeboard for Winter North Atlantic for Well-deck Vessels -- Rules for Depth of Loading of Turret-deck Vessels - Rules for Shelterdeck Vessels - Load Draught Diagrams - Types of Vessels -Freeboard Marks—Freeboard Tables—Freeboards for Freighters - Freeboards for Spar Deckers - Freeboards for Awning Deckers - Sailing Vessels - Kirk's Analysis - Analysis Data - Wetted Surface Formula-Launching-Launching Periods -Launching Curves - Camber of Ways - Declivity of Ways -Pressure on Dog Shoes - Length of Ways - Tables of Launching Data - Calculation of Hull Weights - Ditto by Johnson's Method - Johnson's Curves - Complete Tables of Weights of Steel Shapes - The Transport of Cattle - Arrangement of Stalls and Pens - Dimensions of Stalls and Pens - Board of Agriculture Regulations - Detailed Weights of Cattle Fittings - Rudder Formulæ - Spectacle Frames - Proportions of Spectacle Frames — Propeller Struts — Simpson's Formula for Propeller Struts-Proportions of Brackets-Centre of Gravity by Experiment - Centre of Gravity by Calculation - Strength of Ships - Hogging - Sagging - Curve of Weights - Curve of Buoyancy - Curve of Loads - Curve of Shearing Stresses -Curve of Bending Moments - Specimen Calculations for Moments of Inertia - Diagram of Strength Curves - Resistance of Ships - The Admiralty Constant - Table of Constants for various Types — Froude's Investigations — Law of Comparison -Application of Froude's Law - Speed and Power Curve -Standard Curves of Power - I.H.P. by Independent Method -Skin Resistance — Residuary Resistance Power — Form of Least Resistance — Middendorf's Method — Table of Angles of Entrance and Run — Table of Steamers' Data.

Section II. — Strength of Materials.

Strength of Materials — Ultimate Strength — Working Load — Proof Strength — Stress and Strain — Tensile Stress — Compressive Stress — Shearing Stress — Bending Stress — Torsional Stress — Resilience — Elasticity — Modulus of Elasticity — Permanent Set — Moment of Inertia — Neutral Surface — Section Modulus — Moment of Resistance — Radius of Gyration — Various Stresses and their Factors — Elements of Sections — Beam Bending Moments — Elements of Circular Sections — Moment of Inertia of Circular Sections — Strength of Columns — Johnson's Formula for Columns — Least Radius of Gyration for various Sections

— Values for Johnson's Formula — Pipe Pillars — Standard Pipe Elements — Steel Columns — Strength of Metals and Alloys — Physical Properties of **Timber** — Strength of Timber — Weight and Strength of Wire Rope — Notes on the Use of Wire Rope — Strength of Chain Cables — Proof Load for Chains — Strength of Guard **Chains** — Weight of Chain Cables — Breaking Strength of Chains — Elements of Angles — Elements of Bulb Angles — Elements of Deck Beams — Elements of Tees — **Elements** of Zbars — Tees as Struts — Bending Moments of Pins — Strength of Special Shackles — Riveting U. S. Navy — Standard Rivets — Lloyd's Riveting Table — Tables of Strength of **Riveting** — Ordered Lengths of Rivets — Shearing and Bearing Tables of Rivets.

Section III. — Fittings and Details.

Structural Details — Keels — Bar Keel — Keel Scarphs — Tack Rivets in Keels — Universal Bar — Flat Plate Keels — Centre Keelson - Keel Doublings - Stems - Stern Frames - Braces -Gudgeons - Pintles - Riveting of Boss - Rudder Post - Body Post — Rudders — Single Plate Rudder — Norman Head — Rudder Arms - Coupling Palm - Coupling Bolts - Rudder Stock -Cast Steel Rudder - Balanced Rudders - Heel Bearing - Emergency Chains - Types of Rudder Carriers - Rudder Trunks -Tail Plates - Propeller Struts - Area of Propeller Brackets -Boss Barrel - Spectacle Frames - Bossing around Shafts -Tube-end Castings - Framing - Resistance of Frames - Cut Frames — Pressed Plate Chocks — Stapled Collars — Frame Doublings — Spirketting Plate — Framing of Superstructure — Reverse Frames - Floors - Stresses on Floors - Flanged Floors - Channel Floors — Water-tight Floors — Floor Brackets — End Floors - Inner Bottoms - Water-tight Compartments - Centre Vertical Girder - Side Girders - Margin Plate - Ceiling on Tanks -Bitumastic Cement — Manholes — Tank Bleeders — Beams — Beam Camber — Welded Beam Knees — Bracket Knees — Standard Beam Knees - Strong Beams - Carlings - Deck Girders -Beam Collars - Hold Pillars - Built Columns - Pipe Pillars -Standard Solid Heads and Heels - Fitting of Pillars - Heels on Inner Bottoms — Staggered Pillars — Hatches — Size of Hatches - Hatch Corner Doublings - Corner Angles - Hatch Fore and Afters - Bridle Beams - Standard Hatch Cleats - Battening Bar — Hatch Wedges — Hatch Ledges — Hatch Lashing Rings — Hatch Covers - Lifting Rings - Web Frames - Keelsons - Intercostal Plates - Side Stringers - Bulkhead Collars - Longitudinals — Ending of Keelsons — Bulkheads — Collision Bulkheads - Bulkhead Liners - Bottom Plaiting Bhd. - Stiffeners - Stresses

on Bulkheads - Deep Framing - Caulking - Chafing Pieces -Shell Plating - Arrangement of Strakes - Plate Lines - Fairing the Lines on Model - Shift of Butts - Furnaced Plates - Landings - Butts of Plating - Garboard Strake - Sheerstrake - Shell Riveting — Stealers — Jogging — Scarphs of Overlaps — Liners at Overlaps — Scarphing of Landing Edges on Stem and Stern Post - Holes through Shell-Doubling Plates-Hood End Plates-Doublings at Breaks - Fitting Details - The Preparation of Details - Standardizing Details - Bill of Material - Standard Hatching — Graphic Division of One Inch — Baldt Anchors — Inglefield Anchors — Hall Anchors — Admiral Anchors — Anchor Cranes - Formulas for Bevel and Mitre Gear Blanks - Naval Anchor Crane - Stress on Auchor Cranes - Dimensions of Anchor Cranes - Ship's Bells - Weight of Bells - Belay Pins -Balanced Armor Hatch - Standard Bollards - Weights of Bollards - Wire Rope Snatch Blocks - Diamond Rope Blocks - 25-Ton Block - Standard Iron Blocks - U.S. Standard Bolts and Nuts — Chain Plates — Cast Steel Cleats — Catting Hooks — Crane Hooks - Navy Boat Crane - Boat-handling Arrangement -Rotating Davit - Mallory Davit - Swan-neck Davit - Mine Davit - Board of Trade Rules for Round Davits - Davit Heads -Weights of Boats and Davit Diameters - Standard Hinged W. T. Doors - Standard Sliding W. T. Doors - Details of W. T. Doors - Standard Eyebolts - Standard Fairleads - Weight of Fairleads — Flanges for Lead Pipes — Standard Pipe Flanges — Standard Flanges for Ventilation - Standard Hand Wheels (Iron) -Standard Hand Wheels (Brass) - Hawse Pipe Proportions -Weights of Hawse Pipes — Hooks — Cargo Hooks — Swivel Hooks -Trip Hooks - Keys and Keyways - Reversible Pad Eve-Lewis Bolt - Accommodation Ladders - Lashing Triangles -Mooring Pipes - Strength of W. I. Pipes - Plug Cock Keys -Standard Pad Eyes - Strength of Rings - Proportions of Rings - Ordered Lengths of Rivets - Diagrams for Rivets - Ring Plates - Dimensions of Wood Screws - Areas of Sea Anchors - Detail of Sea Anchor - Sisterhooks - Slip Shackles - Trade Shackles -Standard Shackles - Standard Worked Eyes - Towing Bitts -Steering Chain Springs - Screw Steering Gears - Deck Seats -Weights of sidelights — Proportions of Chain Slips — Boom Mountings — Spider Bands — Torpedo Net Details — Gaff Mountings — Stuffing Boxes and Glands — Thimbles for Wire Rope — Standard Toggle Pins - Admiralty Turnbuckles - Trolley Block - Universal Joints — Low Pressure Valves — Heavy Pressure Valves — Friction Brake for Cranes — Ventilation — Chart for Ventilation Pipes — Terminals for Exhaust Pipes — Adjustable Terminals — Terminals with Dampers - Standard Sizes of Ventilators and Cowls — Weight of Cowls — Elswick Guns — Vickers Guns —

Schneider Guns — Krupp Guns — Bethlehem Guns — U. S. Naval Ordnance.

Section IV—Rigging and Ropes.

Standing Rigging — Table of Wire Rope — Splices — Thimbles — Sheaves — Turnbuckles — Running Rigging — Manila — Hemp — Coir — Blocks — Standard Blocks, U. S. N. — Cargo Blocks — Tackles — Power gained by Blocks — Whip — Double Whip — Guntackle Purchase — Burton — Double Spanish Burton — Luff Tackle — Rigging Derricks.

Section V. - Equipment.

Anchors and Chains — Lloyd's Equipment — Lloyd's Table — Hawsers and Warps — Tables of Equipment — Weights — Mooring Swivel — Blake Stopper — Senhouse Slip — Admiralty Cables — Chain Cable Links — Club Shackle — Chain Swivel — Kenter Shackle — Boats — Notes on Construction — Diagram of Proportions — Lifeboats — Cutters — Dinghies — Gigs — Barges — Galleys — Table of Scantlings for Rowboats — Sail Area — Drawing of Standard Lifeboat in Detail — Lifting Rings and Slings — Board of Trade Requirements — Supervising Inspector's Requirements — Sea Anchors — Axes, Buckets, etc. — Light Screens — Tonnage — Various Tonnage Rules — Y. R. A. and N. Y. Y. C. Rules — Windlasses — Towing Machines, etc.

Section VI. - Miscellaneous.

Tables of Weights — Measures — Oil Fuel Data — Weights of Bolts and Nuts — Tank Capacities — Unit Equivalents — Squares, Cubes, and Fourth Powers of Fractions — Powers and Roots — Speed Tables — Foreign Weights and Measures — Stowages of Merchandise — Cold Storage Temperatures — Distances from Colon.

Section VII. - Tables.

Complete mathematical tables specially arranged.

SYMBOLS COMMON IN NAVAL ARCHITECTURE USED IN THIS BOOK.

	•
S. A	Area of load water plane. Sail area in square feet. Centre of effort of sail plan. Distance of centre of effort forward of centre of immersed lateral plane.
²	Coefficient of fineness of load water line = $\frac{A}{L \times B}$.
b Bm Bx Bw	Bilge diagonal coefficient. Moulded breadth of ship. Extreme breadth of ship. Water-line breadth of ship.
β	Coefficient of midship section area = $\frac{\cancel{\times} A}{B \times d}$.
B	Centre of gravity of displacement (centre of buoyancy). Centre of gravity of displacement from aft perpen-
u	dicular. Centre of gravity of ship above base. Centre of gravity of ship and engines. Moulded depth to upper deck.
D V	Displacement in tons of salt water (gross). Displacement in cubic feet (volume). Displacement in tons at load draught. Displacement in tons at light. Displacement of fore body. Displacement of after body.
D D D 	Displacement in tons at light. Displacement of fore body.
0 · · · · · €	Relation coefficient.
F	Freeboard from statutory deck line. Freeboard to top of rail amidship.
	Coefficient of centre of gravity = $\frac{G}{H}$.
F.P	After perpendicular (after side of rudder post). Forward perpendicular (fore side of stem at upper deck). Indicates the half-length between perpendiculars and is the sign of the mid-section or "dead flat."

The Naval Constructor

```
\mathbf{X}A... Mid-section area.
M.C. . . Height of transverse metacentre above base.
G.Z. . . Stability lever.
G.M. . . Height of transverse metacentre above centre of gravity.
B.M. . . Height of transverse metacentre above centre of buov-
L.M.C. Longitudinal metacentre above base.
\widetilde{G} . . . . Centre of gravity below L.W.L.
G . . . . Centre of gravity above L.W.L.
p . . . . Prismatic coefficient. I.H.P. . Indicated horse power.
E.H.P. . Effective horse power.
N.P. . . Nominal horse power.
B.P... Length of ship between perpendiculars.
W.L. . . Length of ship on load water line.
wl \dots Water line. O.A.\dots Length of ship over all.
R . . . . Placed before dimensions indicates that these are the
             registered or tonnage dimensions.
I.... Moment of inertia of load water plane.
M . . . . Metacentre and moment.
M'' . . . Moment to alter trim one inch at load line.
O . . . . On drawings locates the intersection of projected water
             line with the elevation.
O . . . . Centre of gravity, or moment about centre.
    . . . Centre of gravity of water line.
    . . . Centre of gravity of mid-section area.
(ii) . . . Centre of gravity of sail plan, or centre of effort.
y \dots Ordinates or stations.
x.... Common interval or abscissa between ordinates.
W.S. . . Area of wetted surface.
R . . . . Resistance.
\frac{1}{2} G, or U, Half-girth of midship section (Lloyd's).
d.... Draught of water moulded (mean).
d \rightarrow \dots Draught of water forward
                                        to bottom of keel.
\prec d . . . Draught of water aft
. . . . Mean draught
P . . . Power. V . . . Speed in knots per hour.
                                  D^{3} \times V^{8}
C . . . Admiralty constant = \frac{1}{1 \cdot H \cdot P}.
🙀 . . . . Per.

THE

NAVAL CONSTRUCTOR

CHAPTER I.

DISPLACEMENT (D).

THE displacement of any floating body whether it be a ship, a barrel, a log of lumber or, as in the case of the great Philosopher who first discovered its law, the human person, is simply the amount of water forced or squeezed aside by the body immersed. The Archimedian law on which it is based may be stated as: -All floating bodies on being immersed in a liquid push aside a volume of the liquid equal in weight to the weight of the body immersed. From which it will be evident that the depth to which the body will be immersed in the fluid will depend entirely on the density of the same, as for example in mercury the immersion would be very little indeed compared with salt water, and slightly less in salt water than in fresh. It is from this principle that we are enabled to arrive at the exact weight of a ship, because it is obvious that if we can determine the number of cubic feet, or volume as it is called, in the immersed body of a ship, then, knowing as we do that there are 35 cubic feet of salt water in one ton, this volume divided by 35 will equal the weight or displacement in tons of the vessel. If the vessel were of box form, this would be a simple enough matter, being merely the length by breadth by draught divided by 35, but as the immersed body is of curvilinear form. the problem resolves itself into one requiring the application of one of a number of ingenious methods of calculation, the principal ones in use being (1) The Trapezoidal Rule, (2) Simpson's Rules, and (3) Tchibyscheff's method.

Simpson's First Rule.

The calculation of a curvilinear area by this rule is usually defined as dividing the base into a suitable even number of equal parts, erecting perpendicular ordinates from the base to the curve, and after measuring off the lengths of these ordinates, to the sum

of the end ones, add four times the odd and twice the even ordinates. The total sum multiplied by one third the common interval between these ordinates, will produce the area. It should, however, be stated that the number of equal parts need not necessarily be even, and as it is sometimes desirable to calculate the area to an odd ordinate by taking the sum of the first ordinate and adding to it four times the odd ones, and twice the last as well as the even ordinates into one third the common interval, the area may be calculated accurately. In the foregoing definition it should be noted that the first ordinate is numbered "0," and that the number of intervals multiplied by 3 should equal the sum of the multipliers.

Area of
$$ABCD = \frac{x}{3} (y_0 + 4 y_1 + 2 y_2 + 4 y_3 + y_4).$$

And if half ordinates be inserted between y_0 and y_1 and between y_3 and y_4 we should then have:—

Area =
$$\frac{x}{3} (\frac{1}{2} y_0 + 2 y_{\frac{1}{2}} + 1_{\frac{1}{2}} y_1 + 4 y_2 + 1_{\frac{1}{2}} y_3 + 2 y_{3\frac{1}{2}} + \frac{1}{2} y_4).$$

Should, however, we desire to calculate the area embraced within the limits of y_3 only, omitting the half ordinate y_4 , then:—

Area =
$$\frac{x}{3}$$
 ($y_0 + 4 y_1 + 2 y_2 + 2 y_8$).

So that it is immaterial what subdivision of parts we may use as long as the multiplier is given the relative value to the space it represents as exemplified in the subjoined table. It will be obvious that we may also give multiplier only half its value, as

$$\frac{1}{2}y_0 + 2y_1 + 1y_2 + 2y_3 + \frac{1}{2}y_4$$

and multiply the sum by $\frac{2}{3}$ of x, which will be found the more convenient way to use the rule, involving as it does figuring with smaller values.

Multipliers for Subdivided Intervals.

Ordinates, Multipliers, Ordinates, Multipliers, Ordinates, Multipliers, Ordinates, Multipliers,	0 1 0 1 0 1 0	122141221	$1\\ 1^{\frac{1}{2}}\\ 2\\ 1^{\frac{1}{2}}\\ 1\\ 2\\ 1$	24 $2\frac{1}{2}$ 2 $1\frac{1}{2}$ 2 $1\frac{1}{2}$	3 2 3 342 1 2	4 4 31 1 21 2 2	5 1½ 3½ ½ 3 1½ 3 3 1½ 3 3 3	5½ 1 3¾ 1 4 4 3½ 131	4 5 12 0 11 4	4 1 1 1 2 2 2 5 4	4 1 3 6 3 4 6 11	$4\frac{1}{2}\frac{1}{2}\frac{1}{3}$ $6\frac{1}{4}$ 1	423513514514 64212 7	45623334 64 1	15 167 148 1
----------------------------------------------------------------------------------------------------------------------	---------------------------------	-----------	---------------------------------------------------------	-----------------------------------------------------------	---------------	-----------------------------------	--------------------------------------------------------------	-------------------------------------------	------------------------------	-------------------	------------------	---------------------------------------------------------	----------------------------	---------------------	--------------

As proof of the rule let us deal with an example:

Area
$$ABCD = \frac{x}{3}(y_0 + 4y_1 + y_2)$$
.

Assume curve DFC is part of a common parabola; area DKCFD is $\frac{2}{3}$ area of parallelogram. Join DC, and draw parallel

to GH touching curve. If DFC be part of parabola area, DFC is $\frac{2}{3}$ of parallelogram DCHG.

$$EK = \frac{1}{2}(y_0 + y_1).$$
 $FK = y_1 - \frac{y_0 + y_2}{2}.$

Parallelograms on same base and between same parallels are equal. Draw through G and H two lines parallel to base as GM and DL, then area

$$DCHG = \text{area } DLMG$$

$$= 2 \ x \times DG$$

$$= 2 \ x \times FK$$

$$= 2 \ x \left(y_1 - \frac{y_0 + y_2}{2}\right)$$

Area
$$DFC = \frac{2}{3}$$
 of above $= \frac{4}{3} \left(y_1 - \frac{y_0 + y_2}{2} \right)$
Area $ABCKD = 2 x \left(\frac{y_0}{2} + \frac{y_2}{2} \right)$
Whole area $2 x \left(\frac{y_0}{2} + \frac{y_2}{2} \right) + \frac{4}{3} \left(y_1 - \frac{y_0 + y_2}{2} \right)$
 $= \frac{x}{3} (y_0 + 4 y_1 + y_2).$

Simpson's second rule for determining areas bounded by a parabola of the third order and the "five eight" rule applicable to the calculation of one of the subdivided areas are given in most text-books, but are omitted here as superfluous, Simpson's first rule being adaptable to either of these cases, so that for all ship calculations where areas, volumes, or moments are required, the first rule, or as hereafter explained Tchibyscheff's rule, are recommended.

We have seen, then, how the area or surface may be calculated by this rule, and as the volume is the area by the thickness, it will be evident that if the areas be calculated at various levels or water lines, as shown in the figure, and these areas in turn treated as a curve and integrated by means of the rule, that the result will be the volume of the body.

Let the Figs. 3 and 4 represent the immersed half longitudinal body of a vessel 100 feet long by 12 feet broad submerged to 5 feet draught as represented by L.W.L. It is required to calculate the volume of water displaced by Simpson's first rule. The base line length between perpendiculars should be divided into an equal number of intervals, and as advocated in the chapter on Design, it will be well to have a definite number and retain same for all designs, as by so doing it will facilitate comparisons and working from one design to another. Ten such intervals with half-end ordinates is a very convenient division, and in this case

F1G. 3.

will give a common interval of 10 feet. The draught of 5 feet must likewise be subdivided into a certain number of equal intervals, which in this case we will fix at 4, so that

$$\frac{5 \text{ ft. draught}}{4} = 1.25 \text{ ft.}$$

interval between water lines. These divisions of water lines must be drawn across the body plan of ten sections, and the half breadths read off with a scale and tabulated as in table on following page.

It should be stated in connection with the subdivision of the * base line that the length taken for displacement is measured by some designers from the after side of body post i.e., ignoring the propeller aperture; and by others from the fore side of body post to the after side of stem omitting the moulded size of these forgings. Both of these methods are inaccurate besides leading to confusion, as, in the first case, the displacement of the propeller with its boss will equal the displacement cut out for aperture not to mention the volume of the rudder, which is rarely, if ever, taken into account. And in the second case the tiny amount of displacement added at the knuckle formed by the bearding line of plating when the length is taken to forward and after sides of stem and stern post respectively, is compensated for by the gudgeons on stern post. Therefore the most correct and also the most convenient length is from after side of rudder post to forward side of stem at load water line.

Where vessels have a very flat floor line a half water line should

be taken between base line and first water plane, and the keel or bottom half-breadth given a value proportioned to the rise of floor line as in Fig. 5.

Fig. 5.

Required the half-breadth x at the keel for the displacement sheet, where 10 feet is the actual scaled length L, 6" the rise of floor, 7" the distance from the rise line to first water line at moulded half-breadth of ship and, of course, 13 inches the water line interval, then:—

x = 5.38 feet = bottom breadth.

The displacement to the load water line being 73.82 tons it is useful to know what relation that weight bears to the vessel if she were of box section, in other words, the amount that has been cut off the rectangular block formed by the length, breadth, and draught, to fine it to the required form, or the block coefficient or coefficient of displacement represented by the symbol " δ ". It will be evident that this coefficient may readily be computed by multiplying the length × breadth × draught, and dividing the product, which is the volume of the box in cubic feet, by 35 to get the tons displaced by the rectangular block. The displacement as calculated, divided by this result, will give the block coefficient " δ ", or,

$$\frac{V}{L \times B \times d} = .432$$
 nearly.

The range of this coefficient for various types is given elsewhere in the Table of Element Coefficients.

Area of Water Plane.

	KEEL.	W.L. 1.	W.L. 2.	W.L. 3.	W.L. 4.
Sum of products.	.30 63	25.16 6 ² / ₃	43.34 6 ² / ₃	54.68 63	62.41
Half-areas	2.00	167.73 2	288.93 2	364.53 2	416.07 2
Areas of water planes	4.00	335.46	577.86	729.06	832.14

The area of any of the water planes in the specimen displacement table will simply be the sum of the products of the particular

water plane required, multiplied by \(\frac{2}{3} \) the interval between ordinates. This product doubled will be the total area of both sides.

Tons per Inch of Immersion ("").

It is useful to know the amount of displacement of the vessel for each inch of immersion at various draughts, as from this data small amounts of cargo taken out or placed on board can be accurately determined without reference to, or scaling from, the regular displacement curve. It will be seen that if A represents the area of water plane, that this surface multiplied by a layer 1 inch in thickness and divided by 12 will equal the volume of water displaced in cubic feet at the particular water plane dealt with, and that this volume divided by 35 will equal the displacement in tons for one inch, or in other words, the tons per inch immersion. Or,

$$A \times \frac{1}{12} = \frac{A}{12}$$
 cubic feet,

and the weight of water in the layer

$$\frac{A}{12} \times \frac{1}{35} = \frac{A}{420} =$$
tons per inch.

Tons per inch immersion in salt water,

Tons per inch immersion in fresh water,

$$\frac{\text{area of water plane}}{(12 \times 36) = 432}.$$

So that referring to the table we have been working out, we get: -

	KEEL.	W.L. 1.	W.L. 2.	W.L. 3.	W.L. 4.
Area of water plane	•	•	•_		832.14
	420 .01	$4\overline{\underline{20}}$.79	$egin{array}{c} 4\overline{2}0 \ 1.37 \end{array}$	$4\overline{20} \\ 1.76$	420 1.98 S.W.

It is often necessary to estimate the tons per inch approximately, and for this purpose the coefficient of the load line or "a" is used. The method of arriving at this coefficient is explained in the chapter on design when the displacement is known.

It has a range of about .6 in fine vessels to .9 in exceptionally full ones. In the above example it is found to be

$$\frac{832.14}{\text{Length} \times \text{Breadth}} = \frac{832.14}{1200} = .694.$$

Therefore the tons per inch is equal to

$$\frac{L \times B \times .694}{420} = 1.98.$$

Its relation to the other element coefficients is

$$a = \frac{\delta}{\epsilon \cdot \beta}$$
.

Immersion Passing from Salt to Fresh Water.

From what has been previously said it will be obvious that the draught of water, or immersion of a vessel, will undergo a change in passing from fresh water into the sea or vice versa, owing to the difference in density of the two liquids. If we take the case of the ship passing from salt water to fresh, the immersed volume will be in each case as follows:—

Immersed volume in salt water $\equiv 35 D$, Immersed volume in fresh water $\equiv 36 D$,

where D is the displacement in tons, which in the example we have been investigating equals 73.82 tons. Therefore the volume in cubic feet which the vessel has sunk on entering the fresh water is $36\ D-35\ D=2657-2584=73$ cubic feet. Let T= tons per inch immersion in fresh water $\cdot \cdot$ area of water plane = 432 T and the extent to which the vessel will sink

$$=\frac{73}{432 T}$$
 feet $=\frac{12 \times 73}{432 T \text{ inches}} = \frac{73}{36 T} = 1.02$ inches.

Inversely we have the amount that the vessel emerges in passing out of a river into the ocean. Thickness of the layer which vessel has risen in feet

$$= \frac{\text{Difference in volume } D}{\text{Area of the plane}},$$

and in inches,

$$\frac{\text{Difference in Volume } D \times 12}{\text{Area of water plane}} = \frac{12 \times 73}{420 \ T} = \frac{73}{69.3} = 1.05 \text{ inches.}$$

This immersion and emersion is, of course, the mean amount as the vessel will also slightly change her trim due to the altered position of the centre of gravity of water plane, about which the ship's movements are pivotal.

Area of Midship Section $(\not \in A)$.

The area of this, or any of the other sections on the displacement table, is calculated by taking the half-breadths of the water lines and integrating them as explained for water-line area. The sum of the products thus obtained is multiplied by $\frac{3}{4}$ the distance of water lines apart, and that result by 2 for both sides. Where the vessel has little rise of floor a half water line should be introduced, and the bottom half-breadth proportioned to the rise line, as pointed out in the displacement calculation. In the example with which we are dealing, however, the vessel has considerable rise, so that this subdivision has been omitted.

ORDINATE.	KEEL.	W.L. 1.	W.L. 2.	W. L. 3.	W.L. 4.
"5"	Half- Breadth.	Half- Breadth.	Half- Breadth.	Half- Breadth.	Half- Breadth.
	.02	3.54	5.20	5.80	6.00
Simpson's Multipliers	1/2	2	1	2	1/2

The coefficient of this area, or β , is a very important element of the design as explained elsewhere, and is obtained by dividing the midship area by the area of the rectangle formed by the molded breadth and the draught, or

$$\frac{\text{Mid. area}}{\text{Breadth} \times \text{draught}} = \frac{44.62}{60} = .743 \text{ coefficient of mid. area.}$$

Its relation to the midship-section cylinder or prismatic coefficient "p" is $\frac{\delta}{\beta}$, and "p" is equal to the volume of displacement divided by the length \times mid. area, thus:—

$$p = \frac{V}{L \times A} = \frac{L \times B \times d \times \delta}{L \times B \times d \times \beta} = \frac{\delta}{\beta} = \text{prismatic coefficient,}$$

and consequently, $\beta = \frac{\delta}{p}$

Centre of Buoyancy (C.B.).

The centre of buoyancy of the displaced water is simply its centre of gravity, and its location below the load-water line is greater or less in accordance with the form of the immersed body. This distance may be found by dividing the under-water part into a number of planes parallel to the load line, and multiplying the volumes, lying between these water planes, by their depth below load-water line. These moments divided by the displacement volume will give the location of centre of buoyancy below loadwater plane. So that by taking the functions of the products at each water plane on the sheet we have been working and multiplying them by the number of the water line they represent below L.W.L., and dividing the sum of those products by the sum of the functions referred to, we shall have the number of water-line intervals (or fraction of an interval), which the C.B. is below load-water line. This result, multiplied by the common interval between water lines, will give the required distance in feet.

						×
Water lines a	part .				=	1.25
Centre of bu	ovancv	below W	.L. 4		=	1.86 ft.

The centre of buoyancy may be determined from the displacement curve by calculating the area enclosed within the figure formed by the vertical line representing the draught of 5 ft., the horizontal line equal to the tons displacement at this draught and the curve itself. This area divided by the length of the horizontal line referred to, will give the depth of C.B. below L.W.L. In the present example we have: area = 138.6 sq. feet, and length of horizontal line (displacement in tons) = 73.82, and

$$\frac{138.6}{73.82} = 1.87 \text{ feet,}$$

distance of C.B. below L.W.L.

A like result may also be obtained by taking the sum of the products of each water line, and dividing them by the sum of Simpson's multipliers. The mean half-breadths of water lines so obtained may be then used to draw a mean section of the

vessel on stout paper, which on being cut out with a knife and swung in two positions, the points being intersected afterwards, will give the centre of gravity (buoyancy) very accurately.

Various approximate methods are in vogue for finding this

centre, some of which are fairly accurate.

(1) Approx. C.B. above base =
$$d\left(\frac{5\alpha - 2\delta}{6\alpha}\right)$$
.

(2) Approx. C.B. below L.W.L.
$$=\frac{1}{3}\left(\frac{d}{2}+\frac{V}{A}\right)$$
,

where A is the area of load-water plane.

This centre, as will be explained, has an important bearing on the stability of the ship.

 = .06 Interval C.B. abaft 5.

Common Interval = 10 ft. $\times .06 = 0.6$ ft. C.B. abaft No. 5.

The locus of the centre of buoyancy in a fore-and-aft direction is of course the centre of gravity of the displacement, and is the

pivotal point or fulcrum for the moments of all weights placed forward or aft of this position. It will be obvious, therefore, that its location is of great value in determining the trim of the vessel, and the various alterations thereof due to rearrangements of weights on board. Its position is calculated by taking the areas of the sections and putting them through the multipliers; these functions of areas are in turn multiplied by the number of intervals, (each one is forward or aft of the mid-ordinate,) and the difference between these forward and after moments divided by the sum of the area functions. The quotient resulting is the number (or fraction) of intervals that the centre of buoyancy is forward or aft of the $\frac{1}{2}$ length according as the moment preponderates forward or aft respectively.

This centre should be calculated for various draughts, as of course it changes with different draughts and alterations of trim, owing to the changing relationship between the fineness of fore and after bodies at different immersions and trims.

Transverse Metacentre (M.C.)

The position of this element is, in conjunction with the centre of gravity, the most vital in the design of the ship. As its name implies, it is the centre or point beyond which the centre of gravity of the ship may not be raised without producing unstable equilibrium in the upright position, or, otherwise stated, if the ship be inclined transversely to a small angle of heel, the centre of buoyancy which originally was on the centre line will move outboard to a new position; but, as it acts vertically upward, it must somewhere intersect the centre line. This point of intersection is known as the metacentre. One of the factors in the determination of its location above the centre of buoyancy has already been calculated, viz: the volume of displacement V; the other, the moment of inertia of the water plane about the centre line of ship, we shall proceed to compute. The height M above the C.B. or B.M. is found by:—

$$\frac{\text{Moment of Inertia of Water Plane}}{\text{Volume of Displacement}}, \text{ or, } \frac{I}{V} = \text{B.M.}$$

The moment of inertia of the water plane is a geometrical measure of the resistance of that plane to "upsetting," or when taken about the centre line, as in the case of calculating for transverse metacentre, to "careening." So that the greater the water-line breadth the higher will be its value; for we must imagine the water plane as being divided into a great number of small areas, and each of these multiplied by the square of its distance from the

centre line of ship, when the sum of these products will equal th moment of inertia of half the water plane, about the middle lin of vessel as an axis. As both sides of the water plane are syn metrical, the total *I* will be this result multiplied by 2. Applyin this principle to W.L. 4 in the example with which we are cor cerned, we get the following tabular arrangement:—

Moment of Inertia of Water Plane (I).

	1		T	
ORDI- NATES.	HALF- BREADTHS OF W.L. 4.	CUBES OF HALF- BREADTHS.	Simpson's Mul- tipliers.	PRODUCTS.
0	.04 1.41	2.74	1	2.74
1 12	3.10	29.79	3	22.34
2	4.81	111.28	\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\	222.56
3	5.56	171.88	1 1	171.88
4 5	5.96	211.71	2	423.42
5	6.00	216.00	1 1	216.00
6	5.58	173.74	2	347.48
7	4.87	115.50	1 1	115.50
8	3.57	45.50	2	91.00
9	1.90	6.86	3 1	5.14
$9\frac{1}{2}$.97		1	
10	.03		1 1	
ı	I .	ľ	1	

² / ₃ C.I		• •	•	•	•	•	•		•	1,618.06 6.6 10,787.07
Moment of	Inertia	ı.			•					$. = \overline{7,191.38}$
Volume of	Displac	emer	ıt,	V						. = 2,583.70
	B.M.	$=\frac{I}{V}$	=	$\frac{719}{258}$	$\frac{1.3}{33.7}$	8 7 =	2.	77	ft.	

The calculation for Moment of Inertia and Transverse Met centre above C.B. may be more easily remembered if we treat t cubes of water line half-breadths as the ordinates of a curve tw thirds the area of which will equal I, and this, in turn, divided V will give B.M.

However, when we know a, or the coefficient of water line, way arrive very accurately at the moment of inertia of the wat

plane, and consequently at the B.M. without the labor of the foregoing calculation by multiplying the Length by the Breadth³ by a coefficient, which coefficient will be determined by α and selected from the table given on page 48. By referring to this table, we find for α (value .694) that the coefficient "i" (inertia coefficient) is equal to .0414, whence we get $I = L \times B^3 \times i = 100 \times 12^3 \times .0414 = 7154$ moment of inertia, which is sufficiently close for all purposes, and:—

$$B.M. = \frac{7154}{2583.7} = 2.76.$$

By transposing and taking the calculated I, we find

$$i = \frac{7191}{100 \times 12^8} = .0416.$$

Longitudinal Metacentre (L.M.C.)

From the definition given for the transverse metacentre it will be seen that if the ship be inclined longitudinally, instead of, as in the former case, transversely, through a small angle that the point in which the vertical through the altered C.B. intersects the original one will also give a metacentre known as the longitudinal, or L.M.C. Its principal use and value are in the determination of the moment to alter trim and the pitching qualities of the vessel, or longitudinal stability. It will be obvious that the moment of inertia of the water plane must be taken through an axis at right angles to the previous case, viz., at right angles to the centre line through the centre of gravity of water plane, which will be where the original and new water planes cross one another in a longitudinal view.

L.M.C. above C.B. =
$$\frac{I_1 \text{ of Water Plane about its C.G.}}{\text{Volume of Displacement}}$$
.

Therefore, to calculate the MI_1 , we must figure the moment of inertia with, say, ordinate 5 (or any other one) as an axis when the moment about a parallel axis through the centre of gravity plus the product of the area of water plane multiplied by the square of the distance between the two axes will equal the moment about ordinate 5.

The moment of inertia about the midship ordinate we shall call I, and the distance of the centre of gravity from this station =x. The moment of inertia about the centre of gravity of plane $=I_1$. We then have $I=I_1+Ax^2$, or $I_1=I-Ax^2$. A clearer conception of this will be obtained from the tabulated arrangement.

Longitudinal Metacentre.

			62.41		52.41		324.13

Area of water plane = $62.41 \times (\frac{2}{3} \times 10) \times 2$. = 832.14 square feet.

Distance of centre of flotation abaft ordinate 5

$$=\frac{(67.57-52.41)}{62.41}=2.42$$
 feet.

Moment of inertia of water plane about ordinate 5

$$= 324.13 \times (3 \times 10) \times 10^{2} \times 2 = 432,172 = I.$$

Moment of inertia of water plane about axis through its centre of flotation.

$$= 432,172 - (832.14 \times 2.42^2) = 427,304 = I_1.$$

Longitudinal metacentre above C.B.

$$\frac{I}{V} = \frac{427,304}{2583.7} = 165 \text{ feet} = \text{Longitudinal B.M.}$$

An excellent approximate formula for the longitudinal B.M. is given by J. A. Normand in the 1882 transactions of the I.N.A. Taking the symbols we have been using:—

$$L.B.M. = .0785 \frac{A^2 \times I}{B \times V}.$$

Applying this formula to the vessel with which we are dealing, we find:

L.B.M. =
$$.0735 \frac{832.14^2 \times 100}{12 \times 2583.7} = 164.12$$
 feet.

which is a very close approximation to the calculated result of

We may also use the approximate formula which we applied in the case of the transverse B.M. altered to suit the new axis with a modified coefficient, as:-

$$L.B.M. = L^8 \times B \times i_1$$

Moment to Change Trim (M_1) .

As the centre of gravity of the displacement (or centre of buoyoncy), either in the vertical or the longitudinal direction may be an entirely different locus from the ship's centre of gravity, it is obvious that unless the moment of the weights of the ship and engines, with all equipment weights, balances about the centre of buoyancy we shall have a preponderating moment deflecting the head or stern, as the moment is forward or aft of the C.B., respectively, until the vessel shall have reached a trim in which the pivotal point or C.B. is in the same vertical line as the completed ship's centre of gravity. To determine the moment necessary to produce a change of trim (M_1) in a given ship, it is necessary to know the vertical position of the centre of gravity of the vessel and the height of the longitudinal metacentre (L.M.C.). The former may be calculated in detail or preferably proportioned from a similar type ship whose centre of gravity has been found by experiment; although great accuracy in the location of this centre in calculating the moment is not as important as in the case of G.M. for initial stability, as small variations in its position can only affect re the final result infinitesimally. To investigate the moment affecting the trim, let us move a weight P already on board of the 100foot steamer whose calculations are being figured.

> D =Weight of ship including weight P = 73.82 tons. BM = 165 feet. P = 5 Tons. GM = 160 feet. l = 50 feet (distance moved).

L = 100 feet (length of vessel).

In the figure we have the centre of gravity G to G_1 , and centre of buoyancy from B to B_1 , due to the shifting of the wei P forward for a distance represented by l, giving a moment

$$D \times GG_1 = P \times l$$
, and $GG_1 = \frac{P \times l}{D}$.

The new water line is at W_1L_1 and B_1G_1 are in the same veral and at right angles to it, and the point of intersection of original and new water line at "O" equal to the centre of gradiflotation) of water plane, therefore the triangles GMG_1 , WO and LOL_1 , are of equal angle, so that

$$\frac{GG_1}{GM} = \frac{WW_1}{WO} = \frac{LL_1}{LO} = \frac{WW_1 + LL_1}{WO + LO}$$

But $WW_1 + LL_1$ is the change of trim, and WO + LO is the ler of the vessel = L, then

$$\frac{\text{change of trim}}{L} = \frac{WW_1 + LL_1}{WO + LO};$$

but we have seen that

$$GG_1 = \frac{GM \times \text{change of trim}}{L} = \frac{P \times l}{D}.$$

Then

Change of trim =
$$\frac{P \times l \times L}{D \times GM}$$
 feet.

Substituting the values, we get: —

$$\frac{P \times l \times L}{D \times GM} = \frac{5 \times 50' \times 100'}{73.82 \times 160} = 2.116 \text{ feet} = 24\frac{1}{8} \text{ inches.}$$

Calling this change of trim 24 inches, and assuming that the p of intersection "O" is at the centre of the length, we should l

the stem immersed 12 inches and the stern raised 12 inches from the original water line, the sum of these figures equalling the total change.

Moment to Alter Trim One Inch (M'').

From the foregoing it will be seen that the total change of trim being known for a given moment, inversely we may get the amount necessary to alter the trim for one inch only, this being a convenient unit with which to calculate changes of trim when a complexity of varying conditions are being dealt with. As we have seen $P \times l = M_1$ the moment to change trim, and

Change of trim =
$$\frac{M_1 \times L}{D \times GM}$$
 feet;

therefore,

$$\frac{1}{12}$$
 foot or one inch $=\frac{D \times GM}{12 \times L} = M''$.

Substituting values we have: -

$$M'' = \frac{73.82 \times 160'}{12 \times 100} = 9.84$$
 foot-tons.

In designing preliminary arrangements of vessels, it is necessary that we should know fairly accurately the moment which it will take to alter the trim one inch (M'') to enable us to arrange the principal weights in the ship, and the varying effects on the trim consequent on their alteration in position or removal. For this purpose a close approximation to this moment (M'') is desirable and may be calculated from Normand's formula as follows:

$$M'' = \frac{A^2}{R}.0001725$$
, or $\frac{49^{1/2} \times 30.9}{R}$.

Where A^2 =the square of the water plane area, and B=the greatest breadth of water plane. Applying this approximate formula to the foregoing example, we have:—

$$M'' = \frac{832.14^2}{12} \times .0001725 = 9.95$$
 foot-tons,

as against 9.84 foot-tons found by actual calculations, a difference too insignificant to affect noticeably the change in trim.

This moment is useful to have for various draughts, and consequently should be calculated for light and load conditions, and for one or two intermediate spots and a curve of M" run on the usual sheet of "Curves of Elements."

Alteration in Trim through Shipping a Small Weight.

If it be required to place a weight on board but to retain the same trim, i.e., to float at a draught parallel to the original one, the weight added must be placed vertically above the centre of gravity of the water plane. Should, however, the weight be required in a definite position, then the altered trim will be as under:—

Instead of dealing with the weight at P let us assume firstly that it is placed on board immediately over the C.G. of water plane, when we shall find the parallel immersion to be a layer equal to the distance between WL and W_1L_1 whose depth is $\frac{P}{\Psi}$. Let the weight be now moved to its definite position at a distance

Let the weight be now moved to its definite position at a distance l forward of C.G., then

Change of trim =
$$\frac{P \times l \times L}{(D+P) GM} = C$$
.

GM of course will be the amended height due to altered condition after the addition of P. Then:—

Draught forward =
$$\frac{C}{2} + \frac{P}{\$p''}$$
.

Draught aft = $\frac{C}{2} - \frac{P}{\$p''}$.

Of course we assume that the alteration is of like amount forward as aft. This is only partly correct, but where small weights are dealt with is sufficiently so for most purposes. Generally the ship is fuller aft on and near the load line than forward, and probably a water plane midway between base and L.W.L. would have its centre of flotation at the half length, so that a curve drawn through the centres of gravity of the water planes would incline aft, and as we have assumed the weight as being placed on board over the C.G. of the original water plane, it is obvious that the

new line will have its centre of flotation somewhat further aft, and consequently the tangent of the angle W_1OW_2 will be less than that of L_1OL_2 . With large weights and differences in the two draughts, the disparity would become sufficiently great to require reckoning, in which event the assumed parallel line in the preceding case would give the water line from which to determine the centre of flotation. Thereafter on finding the change of trim, which we shall call 10 inches, the amount of immersion of stem and emersion of stern post would be in proportion to the distance from O to stem and O to post relatively to the length of water line. If we call "O" to stem 60 feet and "O" to post 40 feet, the water line length being 100 feet, we have:—

Immersion forward $\frac{600}{100} \times 10'' = 6$ inches Total change Emersion aft $\frac{100}{100} \times 10 = 4$ inches 10 inches.

TCHIBYSCHEFF'S RULE.

In the preceding pages we have treated with the common application of Simpson's first rule to ship calculations. Another method, equally, if not more simple, which is slowly gaining favor with naval architects is that devised by the Russian Tchibyscheff. This rule has the great advantage of employing fewer figures in its application; more especially is this the case in dealing with stability calculations, and its usefulness in this respect is seen in the tabular arrangement given here. It has the additional advantage of employing a much less number of ordinates to obtain a slightly more accurate result and the use of a more simple arithmetical operation in its working out, viz. addition. As the ordinates, however, are not equidistant, it has the disadvantage of being inconvenient when used in conjunction with designing, and for this reason its use is advocated for the finished displacement sheet and calculations for G.Z.

The rule is based on a similar assumption to Simpson's, but the ordinates are spaced so that addition mostly is employed to find the area. The number of ordinates which it is proposed to use having been selected, the subjoined Table gives the fractions of the half length of base at which they must be spaced, starting always from the half length. The ordinates are then measured off and summed, the addition being divided by the number of the ordinates, giving a mean ordinate, which multiplied by the length of base produces the area:—

 $\frac{\text{Sum of ordinates}}{\text{No. of ordinates}} \times \text{Length of base} = \text{Area.}$

Tchibyscheff's Ordinate Table.

Number of Or- dinates.	DISTANCE OF ORDINATES FROM MIDDLE OF BASE, X, IN FRACTIONS OF HALF THE BASE LENGTH.

The employment of this rule to find the volume of displacement and the other elements usually tabulated on the displace ment sheet is shown on the attached Tables. The number of stations used is ten, as in the case of Simpson's rule, but for clearness the after body five are indicated by Roman numerals, and the fore body ones in Arabic. The displacement length is 600 feet, therefore by taking the fractions given in the preceding table for ten ordinates and multiplying them by 300, we shall obtain the distance of the displacement sections apart. These distances from the half-length and the sections are here given as used for the Table, but it will be observed that the water lines are spaced to suit Simpson's first rule for the vertical sections as no advantage would be gained by the use of Tchibyscheff in this direction, owing to the fewer number of water lines generally necessary. The various operations in the Table will be clearly understood from the headlines of the respective columns.

As already pointed out, the great value of this rule is in the calculations to obtain cross curves of stability, specimen tables of which are also given. The fewness of the sections necessary, and the fact that the integrator saves the calculator the tedium of adding up, tells greatly in favor of the adoption of this rule for these calculations both as a time saver and an eliminator of the chances

of error.

Explanation of Table

EXPLANATION OF TABLE, GIVING EFFECT FORM OF WATER LINE ON POSITION OF LONGITUDINAL METACENTER.

Longitudinal and Lateral Stability Compared. — first four lines are exactly the same as those in the other ta and the last eight lines differ only in having length and breatherchanged, so as to give pitching instead of rolling.

On comparing them with the following table, it will be not that, in the algebraic factor, the length and breadth always in change; and that the numerical factor remains unchanged forms (1), (3), and (A), namely, the square or rectangle, circle or ellipse, and the wedge. Of the nine forms selected, t are obviously the only ones in which breadth and length

absolutely interchangeable.

With respect to the comparison of the different forms, one another, if we disregard the wave-bow No. (8), the variatio stability follows much the same sequence for longitudinal as lateral stability, but with a somewhat less absolute value. result might be expected à priori, because the extreme bre ordinate cuts the outline at right angles in all but the w form (9); while the extreme length ordinate meets the ou more sharply. In forms (2) and (4) this difference is onl the second order; but, as the figures show, it is quite sufficience of practical importance even in these.

Differ Chiefly in Wave-Bow.—The wave-bow forn falls altogether out of its sequence, and its stability is less the wedge form (9) as regards pitching. This is due to sudden falling off of the extreme ordinate length, which n the curve tangentially, instead of normally, as the extibreadth ordinate.

Fine Bow Affects Pitch More than Rolling.—I: consider rolling on any given axis, it is easily seen from geom cal considerations, and also from the algebraic form of the gral, that the instantaneous stability depends, firstly, on the left the transverse axis, and, secondly, on the slowness of the of diminution of that axis, as we pass along that axis of mo Hence sharp bows have less stability for pitching than bluff b while their lateral stability for rolling is not so very different.

Caution in Use of Table. — In the table of lateral stabi the element of length only appears as a simple factor; there as regards lateral stability, we may compound the moment simple addition for a vessel built up in different lengths for the different forms. Thus, the values in lines 1 to 8 of column (2) are simply the means of the corresponding values in columns (1) and (3). We cannot apply this process to the longitudinal stability because here the length element enters as a cubic factor. If we were so to compound the moments of length, what we should really do would be equivalent to screwing together two longitudinal halves of different vessels; in the case before mentioned, screwing half a box to half a tub; not introducing a flat midship length between two semicircular ends.

Explanation of Table Giving Effect of Form of Water Line on Position of Metacenter.

Explanation of Table.—By the preceding table we can at once make an approximate estimate of the value of any proposed form of water line, by selecting that form in the table to which it comes nearest. From this table we gather that the more nearly the water line approaches to a right parallelogram, the more it will contribute to the stability of a ship. No. 9, on the contrary, the straight line wedge form, is the least stable of these water lines, and from the comparison of the successive groups of lines on the table we shall see exactly how this comes about.

Areas on Water Lines. — The first and second lines in the table give the measures simply of the areas of those water lines. From lines 3 and 4 we see that, Fig. 1 being taken as the standard of comparison, Fig. 2 only contains 89 per cent of the rectangular area, and this diminution is effected merely by rounding off the rectangular corners, the length and breadth remaining the same in both. In Fig. 3, when the curvature of the ends extends quite to the middle of the water line, its area is reduced to 69 per cent. In Fig. 6, by forming the water line of parabolic arcs, a favorite form of some builders, the area is reduced to two-thirds of the rectangle. Figs. 7 and 8 are the lines used for a wave stern and a wave bow; from which it appears at once how much more powerful the stern contributed to the stability of a ship than the bow; the stern line being 62 per cent, and the bow line only 50 per cent.

Metacentric Moments. — Lines 5 and 6 are the actual measure of the stability (by its moments) for small inclinations. For example: in the rectangle, the moment is one-twelfth part of the product of the length by the cube of the breadth, or .08 of that product; and as we pass along line 6 we find it gradually diminish, until, in the wedge form, it is only .02, showing that a sharp wedge form has only one-fourth part of the power to carry top weight that the rectangular form has, although its power of buoyancy, or power to carry absolute load, is one-half. This is set out more fully in lines 7 and 8; so that by carefully comparing together line 4 and line 8, the relative values of all those figures for carrying absolute weight and for carrying top weight may be clearly seen.

Metacentrio Intervals. — Lines 9 and 10 measure the powers of ships, formed on these water lines only to carry top weight without upsetting.

[‡] These are all areas or moments, and therefore, for compound forms, it is only necessary to add them, or take a mean of them, as may suit the particular case.

[§] The entries in these lines assume that the vessel is flat-bottomed, with vertical sides. The other entries hold good, whatever may be the shape of the vessel under water. In general, the height of the metacenter may be found by dividing the entry in lines 5 or 6 by the displacement.

Modulus of Fineness.—Lines 11 and 12 enable us to compare the different forms; and by running our eye along line 12 we are enabled to trace the effect of the successive changes in the form of water line, in bringing down the metacenter, and reducing the stability of the ship, thus giving what has been sometimes called the modulus of fineness of water line.

STABILITY CALCULATION, USING THE INTEGRATOR AND APPLYING TCHIBYSCHEFF'S RULE.

The following tables will show the application of the above rule to the calculation of the stability levers GZ from the body plan reproduced, noting that the integrator used was metrically divided, and the original drawing was to a scale of $\frac{1}{4}$ to the foot or $\frac{1}{16}$ full size with ten Tchibyscheff ordinates. The center of gravity was assumed at 24 feet above base. The coefficients are therefore as follows, the length of vessel being 600 feet:—

For displacements (tons),

$$\frac{600}{10} \times \frac{96^2 \times 3.281^2}{100 \times 35} = 1701.5.$$

For levers (feet),

$$.06 \times 96 \times 3.281 = 18.9$$

and,

Displacement in tons =

 $1701.5 \times \text{sum of differences of area readings.}$

Levers in feet = $\frac{18.9 \times \text{sum of differences of moment readings}}{\text{Sum of differences of area readings}}$

Displacements $(D) = 1701.5 \times I$ I respective to II taken up Levers $(GZ) = 18.9 \times \frac{II}{I}$ to the corresponding water

The angles calculated were 15°, 30°, 45°, 60°, 75°, and 90°, and the results as tabulated used to plot off the Stability Cross Curves shown from which the Stability Curves at various displacements were taken, the correction being calculated for the new loci of the center of gravity where G is the assumed position below S then GZ = SZ + SG sin θ , and when above S then GZ = SZ - SG sin θ . So that taking the ordinates from the cross curves at the displacement dealt with SG being now known, we can determine the exact values of GZ for any angle.

CHAPTER II.

DESIGN.

In the foregoing pages we have treated with the various calculations which confront the naval architect, but the relation of these to one another and to the particular qualities that the projected ship shall possess belong to Design.

In designing the ship, nothing should be left to chance, or what is the same thing — trial and error. The vessel must first be designed with figures. Before a single line is run on paper, the various element coefficients should be carefully selected and their functions worked out in consonance with the results desiderated in the finished ship. The relation of these coefficients to one another must be firstly mastered for all types of vessels and conditions of draught and trade, when with the aid of the tables given an unerring selection will be possible and a definite result attained.

When the way is prepared for the drawing part of the design to be taken in hand, it will be found advantageous to have a definite routine in which to prepare the various views comprised under the general term "Lines." Each step should be taken in its proper time and order. Much time will thus be gained, and a clearer conception of the art of designing obtained. To this end we submit the following method as one fulfilling these propositions, dividing the task broadly into two parts, viz.:—

(a) Figures and (b) Lines, the first embracing the moulded dimensions, draught, element coefficients, and their functions, and the latter, the sheer draught, half-breadth, and body plans.

The shipowner will specify the trade for which the ship is intended and the limit of draught on the particular service proposed. It will generally be found economical to take advantage of the maximum draught permissible. When the dimensions are solved to meet the requirements stipulated, the grade numerals should be worked out, for the Classification Society's Rules in which it is proposed to class the ship, and if it be found that a grade can be saved either in plating, framing or equipment numerals, or the requirements for extreme proportions evaded by a slight alteration or adjustment of the dimensions, this of course should be done.

As an example we shall postulate that the shipowner requires a 3-deck freighter with complete shelter deck to carry 10,000 tons dead weight, exclusive of coal for 12 days' steaming, fresh water and stores, on a mean draught of 27 feet with a B.T. Freeboard and a sea speed of 12 knots. The ship to be classed in American Record and to conform to the U.S. Inspection Laws. To these

demands of the owner the naval architect should add the G.M. when fully loaded with a homogeneous cargo. Let us call this 1.5 ft.

The first point to determine is the amount of displacement we shall require to provide for over and above the specified dead weight of 10,000 tons, to allow for weight of finished ship and machinery, coal, fresh water, and stores. At this stage we cannot calculate these items, as we are uninformed as to the dimensions of the ship, so that the remaining method to solve this is to estimate a weight embracing all of these items based on a percentage of the dead weight. This percentage of course is determined from vessels of similar type and trade duly worked out and tabulated by the naval architect. We shall take, then, each step in its proper order:

- (1) Displacement = dead weight $\times 1.64 = 16,400$ tons.
- (2) Block coefficient " δ " = $\alpha \cdot \beta \cdot \epsilon \cdot = .79$.
- (3) Relation coefficient " ϵ " = $\frac{\delta}{\alpha R}$ = .945.*
- (4) Mid. area coefficient " β " = $\frac{\delta}{2}$ = .97.
- (5) Prismatic coefficient "p" = $\frac{\delta}{\beta}$ = .814.
- (6) Area of L.W.L. coefficient "a" = $\frac{p}{a}$ = .861.
- (7) Moment of inertia coefficient "i" (see table) = .0638.
- (8) B.M. coefficient " $m'' = \frac{i}{\bar{s}} = .08$.
- (9) Center of gravity coefficient "g" = $\frac{G}{H}$ = .559. (See table.)
- (10) Depth "H" to upper deck per Freeboard Tables = 33.5 ft.
- (11) Depth " H_1 " to shelter deck = H + 7.5 ft. = 41 ft.
- (12) Center of gravity above base $= H_1 \times g = 41 \times .559 = 22.90$ ft. (13) Metacenter above base = C.G. + G.M.
- = 22.90 + 1.50 = 24.40 ft.
- (14) Breadth "B" to give M.C. of 24.4 ft. =

$$\sqrt{\left[M-d\left(\frac{5\alpha-2\delta}{6\alpha}\right)\right]\times\frac{d}{m}}=58.5 \text{ feet, and } M=\frac{B^2\times m}{d}+d\frac{(5\alpha-2\delta)}{6\alpha}.$$

(15) Length "L" =
$$\frac{V_{\bullet \downarrow}}{B \times d \times \delta}$$
 = 460 ft.

(16) B.M.
$$=\frac{L \times B^3 \times i}{V} = \frac{I}{V} = 10.23 \text{ ft.}$$

(17) Center of buoyancy above base $=d\left(\frac{5a-2\delta}{6a}\right)=14.25 \text{ ft.}$

* May be taken constant .9, as per table.

- (18) Bilge diagonal coefficient (see diagram) = .82.
- (19) Dimensions as determined = $460 \times 58' 6'' \times 33' 6''$.

(20) Displacement "D" = $\frac{460' \times 58.5' \times 27'}{25} \times .79 = 16,400 \text{ tons.}$

(21) Calculated weights: Hull complete 4,670 tons 730 (4,000 I.H.P.) Machinery. . 750 Coal. . . (for 12 days) " 200 Fresh water " 50 Stores . . 6,400 Dead weight . . 10,000 16,400 tons Displacement

Should it be found, however, that the weights calculated for the dimensions as worked out are lighter than anticipated when we started with the 64 per cent of the dead weight, the length should be reduced accordingly. On the other hand, if the weights be excessive, the length must be increased. The length is the only dimension that should be adjusted, as it is the one factor which has no vital relationship to the element coefficients, as it will have been noticed that the primary quality aimed at was the G.M. as a measure of the ship's initial stability; and as the center of gravity varies with the depth, so the metacentric height is dependent on the breadth and draught.

For the preliminary design it will be sufficiently close to estimate the machinery weights on the I.H.P. required, and for ordinary merchant practice the power may be calculated fairly accurately by the Admiralty constant with the formula:—

$$I.H.P. = \frac{D^3 \times V^3}{C}.$$

We then have for the present example, with constant = 267, speed 12 knots, and displacement 16,400, an indicated horse-power = 4000. By referring to the table given elsewhere, it will be found that for twin screw freight steamers with this speed that the I.H.P. per ton of engine boilers and water equals about 5.5, so that we get for a total machinery weight

$$\frac{4000}{5.5}$$
 = 730 tons.

The displacement and coefficients should, in all cases of steel steamers, be calculated to the moulded line of frames, the excess water displaced by the shell plating, amounting to about 1%, being retained in hand as a margin against contingencies. In this case its value is 164 tons, representing 3 inches of draught.

^{*} See Table of Constants, and chapter on Resistance.

Relation of the Coefficients to One Another.

Relation coefficient, $\epsilon = .9$, constant $= \frac{p}{a}$. Block coefficient, $\delta = a.\beta.\epsilon$. Area of water line coefficient, $\alpha = \frac{p}{\epsilon}$, or $\frac{\delta}{\beta.\epsilon}$.

Mid. area coefficient, $\beta = \frac{\delta}{p}$, or $\frac{\delta}{a.\epsilon}$.

Prismatic coefficient, $p = \frac{\delta}{\beta}$.

Bilge diagonal coefficient,

$$b = \frac{p}{.92}$$
 to $\frac{p}{.99}$ ($p = .6$ to .82).

All the elements insuring the qualities that embody a well-shaped boat of the particular type contemplated and at the same time a stable ship having been thus determined, the lines may be commenced with the certainty that no unnecessary alterations will be required.

The freeboard will be calculated from the legal tables given and explained herein, but in any case the limiting draught consistent with the block coefficient determined on as the maximum available for the required speed should be taken advantage of.

After carefully drawing the center and other construction lines, and marking off the ten or twenty ordinates that it is proposed to

and,

use, it will be well to have a definite routine or method in which to draw down the various views comprising what are embraced under the general term "lines."

To this end the following will prove a good sequence:

- 1. The "dead flat" section on body view.
- 2. Rail sheer line.
- 3. Contour of stem and stern in profile.
- 4. Rail half-breadth.
- 5. Load water line half-breadth.
- 6. Bilge diagonal.
- Transfer L.W.L. and B.D. ½-breadths to body plan.
 Draw freehand the sections to foregoing.
- 9. Trial displacement by planimeter.
- 10. Sheer heights from profile to body plan.

Taking this routine in order:—

1st. The dead flat or midship section should present no difficul ties, as the area of this section is pre-determined from the co efficient β . This being so, the height of rise of floor construction line is assigned by giving the easiest bilge consistent with th area of section demanded. In no case should the bilge b "squarer" than the demands of this area require, as in ful vessels sufficient difficulty is encountered in setting the bilge strak plates and bending the frames without adding further to it.

2d. In most vessels, except yachts and launches, it will b found advisable to make the lowest part of sheer at the half-lengt. amidships, as otherwise correction would have to be made fo freeboard and the classification societies' numerals. It is best then, after fixing the height of bulwark or sheer strake abov upper deck to underside of moulding, to run a pencil line paralle to L.W.L. from A.P. to F.P., at which points and above this lin the sheer forward and aft should be set up. The amount of shee will of course depend on the type of vessel, i.e. whether intende for sea or river. In the latter case it is evident the same amour of "spring" would not be required as for over-sea voyages. standard sheer prescribed by the British freeboard tables will be however, a good guide, and where this is deemed insufficient c where special cases suggest a departure from these, as in passenge steamers and first class ocean liners, a handy rule and one that give a very symmetrical sheer is to take one-fifth of the vessel's lengt in feet, calling the quotient inches which will equal the amour of sheer forward. One-third of this will be the sheer aft, as: -

Length in feet = Sheer forward in inches, Sheer forward = Sheer aft in inches.

The amount of sheer having been decided upon with the lowest part, say, at the half-length, the quickest and simplest way to run the sheer line, insuring a fair curve, will be to divide the half-length before and abatt the lowest sheer, into four equal parts, and at each of these points set up the perpendicular heights obtained, as under, postulating in this case that the sheer at F.P. is equal to 82 inches, and the sheer at A.P. 30 inches, giving a mean sheer of 56 inches, as per freeboard tables.

```
82'' \times 1.000 = 82'' sheer at 4th station = F.P.

82'' \times .562 = 46'' sheer at 3rd station forward of lowest

82'' \times .250 = 20\frac{1}{2}'' sheer at 2d station forward of "

82'' \times .0625 = 5\frac{1}{8}'' sheer at 1st station forward of "

and for the sheer aft:—

30'' \times 1.000 = 30'' sheer at 4th station = A.P.

30'' \times .562 = 16\frac{7}{8}'' sheer at 3d station abaft lowest

30'' \times .250 = 7\frac{1}{2}'' sheer at 2d station abaft "

30'' \times .0625 = 1\frac{7}{8}'' sheer at 1st station abaft "
```

By pinning the spline to these spots and adjusting the free ends to the eye, an absolutely fair sheer line may be run in, bearing in mind, however, that in ships with a very full rail line forward, compensation must be given on the sheer to adjust the great disparity in the length of the half-breadth rail line and the same line projected on sheer plan; as, if this be not done, the rail line on model, and of course on the actual ship, will appear as "rounding down."

3d. The contour line of the stem will be very much a matter of individual taste, although above water line it is usual to make it straight unless in special cases. By "straight" is meant "apparently" so, as it is customary to give about \subseteq-inch round on face of stem from where it leaves the top of the forefoot curve to stem head, an absolutely straight line adjoining a curve appearing as slightly hollow. Also, it is not advisable to make the stem plumb, as the illusion in that case is to make it appear as leaning aft. A rake forward of about twice the moulding of the stem head is common. In outlining the stern and counter the same remarks as to taste apply, care being taken that the counter line where it meets the rudder post is carried by an imaginary curve to harmoniously meet the arch of body post. The counter line, from knuckle moulding to stern post, should be perfectly straight - not hollow. A hollow to this line gives the appearance of an overweighted overhang, and a broken sheer, besides making the plating more difficult to set.

The length of overhang of course cannot be arbitrarily fixed but a very fair proportion for ordinary freighters is $\frac{1}{3^{\circ}}$ to $\frac{1}{3^{\circ}}$ of the length. The height of deck or rail at taffrail, or "cock-up," will be dependent on the camber of deck at transom frame (No. 0) The midship camber proportioned to the half-breadth at this frame should be set up and the deck line carried through this spot in a fair curve to taffrail. The height so obtained should be then transferred to body plan, and the deck (or rail line) between No. 0 section and taffrail drawn in as a round of beam curve, from

which may be obtained the intermediate spots for deck at side (or

rail) on sheer plan.

4th. The rail half-breadth will depend on the particular type of ship being designed. In freighters it will be parallel to the center line for probably half the length amidships, whereas in vachts and other fine vessels it will "round" all the way. It is convenient to have rail half-breadths at hand for various types of vessels for, say, ten ordinates with half-end ordinates or whichever number is adopted as the standard. These should be tabulated with the half-breadth amidships as unity, when, with the aid of a slide rule, the half-breadths for the design may be very rapidly proportioned. It will be found convenient to have these for liners, freighters, sound and river steamers, yachts, etc., from good examples of their respective classes. The contour of rail line around taffrail will require careful fairing into the A.P. ordinate spot, and also at center line, where in no case should it be perfectly straight, the effect of such being a hollow. Neither, on the other hand, should it come to a "peak" or point, but carefully drawn as an arc of a circle. The knuckle mouldings, whether they be one or more, may with advantage be delineated by tracing the rail line just drawn and transferring it forward to its exact location. 'By so doing it will be seen that the stern between knuckle and rail lines will develop with a pleasing gradation from "O" frame to the upper counter line.

5th. The load water line, as already stated, must circumscribe the area calculated with the aid of the coefficient a. The method of obtaining a has been previously explained. To obtain the form of this water line, and at the same time insure the accuracy of the required enclosed area, it will be found advantageous to prepare a diagram similar to the one opposite, or this one may be used with the aid of proportional compasses. Opposite the value of a for the design in hand half-breadths for ten ordinates may be read off and transferred to the half-breadth plan. Should, however, the line delineated after the spline has been fixed not meet with the designer's individual taste, or where greater fullness or fineness is required for special cases, forward or aft, it will be a very simple matter to modify the line, at the same time observing that whatever area be cut off at any one point be compensated for elsewhere on the water line, as the offsets taken from the diagram will enclose exactly the area required. Of course the designer may make his own diagram for the number of ordinates he prefers to design with. In any case the run of the line for a few feet forward of the post will require special adjusting when the oxter is being faired.

In addition to the diagram, the following table is given of actual load water lines of several types with the coefficients of area of same (a).

Load Line Half-Breadths Standardized.

6th. The construction line for the bilge diagonal is variously drawn from rise line or base line; but the latter is the more useful, being adaptable to extremes of types and unaffected by rise of floor line; i.e., the line should be drawn diagonally across the

DIAGRAM OF BILGE DIAGONAL OFFSETS FOR VARIOUS VALUES OF "b"

VALUES OF b (COEFF.OF B.D.)
Fro. 13.

body plan from the intersection of the base with the half moulde breadth line to center line at load water line height. It is evident that the area enclosed by this line must bear a close relation

ship to the prismatic coefficient which varies with p and is equal to $\frac{p}{.92}$ to $\frac{p}{.99}$ where p ranges from .60 to .82, respectively.

By determining the value of the bilge diagonal coefficient "b," and referring to the diagram opposite, the offsets for a line enclosing an equivalent area may be taken off and run as a half-breadth line.

DIAGRAM OF L. W. L. HALF-BREADTHS FOR VARIOUS VALUES OF "«" (TEN ORDINATES)

VALUES OF α" (COEFF. OF L.W.L.) Fig. 14,

7th. The load water line and bilge diagonal half-breadths having been preliminarily faired, may be lifted off on a slip of paper and transferred to body plan construction lines, when there should be no difficulty in drawing in freehand the sections, having the "dead flat" section as one extreme guiding curve and the transom frame as the other.

8th. After the preceding sections have been carefully outlined

Fig. 15.

to eye with the guide spots mentioned, the planimeter should be used to take a trial displacement, on the result of which will depend how near the designer's judgment has determined the true section line. In any case he cannot have got far away, and a very slight alteration (if any) is all that will be required.

9th. The sheer heights may now be taken from profile and spotted on body plan, level lines being struck across at these

heights on which to set off the rail half-breadths previously run in plan, as described in paragraph 4. This will enable the completed body plan to be drawn in approximately, from which spots may

be obtained to fair up.

Having got thus far, the final work of fairing will be a compara tively easy matter. A buttock line half-way out on the counte will prove a very useful line for this purpose, thereafter taking buttock and water line alternately until the whole body is faired Where great fairness is required, a complete set of diagonal line should be run; but ordinarily this is unnecessary, unless in smal craft where the sections are intended directly for the floor with

out further fairing.

The following will prove a suitable method for designing and fairing the bossed plating enclosing after-end of shafting. ing determined the outside diameter of the boss of spectacle frame lay off the distance to outer edge of boss barrel at forward end o same on the half-breadth plan, as at A. Then take another spo at the fore end of the stern tube equal to the siding of the vessel' bulkhead frame plus one inch clear of the stuffing box flange or the stern tube bulkhead at "C." Through these two spots con tinue a straight line until it intersects the water plane at the shaf center level "D." The angular space formed by the junction o

Fig. 16.

the water plane mentioned and the projected line should then b carefully faired into the eye with a spline, when the resulting lin will give you half-breadths at the shaft center height. These half breadths being transferred to the body plan, radii should be struck through them giving the contour of the bossing, which may b continued freehand into the frame sections above and below th boss, observing that the general tone harmonizes with the outlinof spectacle frame previously drawn in, in accordance with the form advocated under that heading.

Having outlined the form of bossing on body plan, three diago nal lines should be struck, the lower one intersecting the arc forming oxter under spectacle frame, the middle one through the center of shaft, as shown to diagonal 1½, and the other making a like intersection with the curves of the slope, as shown on the diagram. These diagonals may now be lifted off and run in the

Level lines as shown at l_2 , l_4 , l_6 , etc., are now drawn from the point of intersection of frame with diagonals 1 and 2, and the half-breadths taken off at these levels and finally faired-up on half-breadth, when it will be found that the resulting horizontal ribband line, besides acting as a check on the fairness of the diagonals, will show the "wind" of the shell plating wrapping into oxter and body post and insuring a natural "snye" without any chance of "gather" or unfairness.

The oxter underneath the ship's counter may be faired in a

similar manner.

CHAPTER III.

THE PREPARATION OF SPECIFICATIONS.

Too much care cannot be expended in the drafting of the hul Clearness and conciseness should be aimed at specification. consistent with an embodiment of all details of hull, fittings, and outfits supposed to be supplied, and all repetition or ambiguity of phraseology carefully avoided. Hampering restrictions should be left out. Know your requirements and state them distinctly As in all other ship construction work, it will pay to have a definite routine or system in which to draft the specification. Of course, it is obviously impossible to have a standard specification which shall apply to all ships, as vessels are so diverse in their types, design, construction, and equipment as to make this ar impossibility. But by keeping a routine list of headings of paragraphs before one, and taking these in rotation when drafting the clauses, the liability to omit important requirements is reduced to a minimum, besides the saving in time and distraction of thoughts through having to recollect what comes next. For this purpose the following headings have been selected which will apply to ordinary vessels. Of course, for special types these will require modifications and additions which will suggest themselves.

Specification Headings.

Title giving type of vessel.

1. Dimensions, moulded length, breadth and depth, depth of hold, load draft and deadweight.

2. Classification. The Government laws to which the vessel and her equipment are to conform, also full particulars of the class she is to take at the Classification Society concerned.

3. General Description. Type of stem and stern, number of decks, laid or otherwise, length and character of erections, number of masts. Number of passengers, description of housing of passengers, officers, and crew. Nature of cargo and handling appliances. Location of machinery and any special features of the vessel.

- 4. Material of hull and rivets.5. Keel, and centre girder in
- double bottom ships.

 6. Bilge or side fenders and mouldings, docking keels
- 7. Stein.
- 8. Stern frame.

- 9. Shaft brackets.
- Rudder and stock (also trunk and bearing).
- Shell plating.
- 12. Inner bottom, including plating, side girders, floors and margin plate.
- Scantling in machinery space.
- 14. Peak tanks.
- 15. Deep tanks.
- 16. F. W. storage tanks.
- 17. Steel decks and flats.
- 18. Transverse bulkheads.
- 19. Longitudinal bulkheads.
- 20. Bunkers, oil or coal.
- 21. Engine and boiler casings.
- 22. Shaft tunnels.
- 23. Oil trunks, expansion.
- 24. Centre keelson (in single-
- 25. Side keelsons bottomed ships.
- 26. Hold and 'tween deck stringers.
- 27. Panting arrangements.
- 28. Frames and reverse frames, in double bottom, up sides and at ends.
- 29. Floors, throughout in single-bottomed ships, at ends and tail brackets in double bottom ships, also reference to No. 12.
- 30. Web frames.
- 31. Deck beams and knee brackets.
- 32. Stanchions to beams.
- 33. Strong beams in E. and B. space.
- 34. Hatchways and coamings, in oil or cargo spaces, covers, fore and afters, bearers, etc.
- 35. Cargo and coal ports.
- 36. Grain trimming hatches.
- 37. Chain lockers.

- 38. Machinery Foundations; main, auxiliary and deck machinery, also boiler saddles and shaft and thrust bearing seats.
- 39. Sheet steel bulkheads.
- 40. Steel deck houses, other than erections.
- 41. Bridges, navigating or docking.
- 42. Steel masts.
- 43. Steel kingposts.
- 44. Steel derricks, spars, etc.
- 45. Wood masts, kingposts and spars.
- 46. Wood decks.
- 47. Wood deck houses.
- 48. Ceiling and sparring.
- 49. Boat stowage.
- 50. Anchor stowage.
- 51. Watertight doors and scuttles.
- General description of joiner work, including entrances and stairways:
- 52. In passengers' quarters.
- 53. In officers' quarters.
- 54. In crew's quarters.
- 55. Pantry accommodations.
- 56. Galley accommodations.
- 57. Ice room.
- 58. Sidelights and decklights;
 - also borrowed lights.
- 59. Cattle fittings.
- 60. Hawse pipes.
- 61. Bollards and fairleads.
- 62. Hold ladders.
- 63. Ladders to erections and bridges.
- Davits, boat and anchor, also provision or coaling davits.
- 65. Rails, bulwarks, also rail and awning stanchions.
- 66. Standing and running rigging, including cargo boom handling gear.

67. Sails, covers, and awnings.

68. Cement and tiling.

69. Paint work.

70. Heating system.

71. Lighting system.

72. Ventilating.

72a. Refrigerating system.

73. Deck Machinery, including windlass, winches and capstan, also steam and exhaust piping.

74. Fresh and salt water service.

75. Fire, pumping and draining system.

75a. Cargo oil system.

76. Scuppers, from all exposed houses, etc., and from sanitary quarters.

77. Engine room and docking telegraphs.

77a. Steering gear.

78. Anchors, chains, and line outfit.

79. Boats and outfits.

80. Flags, etc.

81. Hose, fire and wash deck, also fire buckets.

82. Oil tanks, for lamps, etc.

83. Steaming lights.

84. Lamps and lanterns, also rockets, etc.

85. Navigating instruments.

86. Boatswain's stores.

87. Carpenter's stores.

88. Cargo handling gear, slings, hooks, etc.

89. Cook's or galley outfit.

90. Cabin outfit.

91. Cutlery outfit.

92. Crockery and glass.

93. Table linen.

94. Bed linen and bedding.

95. Spare glasses for side-lights in passenger ships.

96. Galvanizing.

97. Trim and stability.

98. Plans to be furnished own-

Capacity and deadweight.

General arrangement.

Cabin booking plans. Piping plans.

Stability curves

information.

99. Docking.

100. Trial trips.

101. Inspection fees (class, etc).

102. General clause relating to material, workmanship, inspection by owners, alterations, extras, etc.

Flags.

National colors.
House flags, and burgee with name.
International signal code.

Boat Outfit.

Ash oars, thole pins or rowlocks. Rudder (lanyard).

Tiller (lanyard).
Painter, 5 fathom line.

Cable, 20 fathom line.

Boat hook.

Water breakers.

Bread tank.

Plugs for bung hole; 2, with chain.

One anchor.

One sea anchor.

One bailer.

One mast yard and sail.

One compass 4" card in case. Four oil lanterns to burn 8

hours.
Four oil distributers, 1 gallon

Twelve boat hatchets.

Boatswain's Stores.

Watch tackles. Relieving tackles. Luff tackles. Spare blocks, double and single, assorted. Spare sheaves, for boat falls. Snatch blocks. Cargo gins. Deck scrubbers. Wood fenders, with lanyards. Cork fenders, with lanyards. Marline spikes. Crowbars. Chain hooks. Chain slings. Hair crate hooks. Screw shackles. Pairs of grip-hooks. Pairs of case-hooks. Coir brooms and handles. Mods. Ballast shovels. Scrapers, triangular. Scrapers, steel file. Set of funnel blocks and boards. Boatswain's chairs, one to each mast. Pilot ladder. Five-inch portable fire engine pump with hose. Bath bricks. Hand spikes. Paint scrubbers. Pairs of handcuffs. Branding iron. Paint brushes, assorted. Paint pots, one-half gallon. Squeegees, large. Scraping box, tin. Sewing palms. Needles. Beam clamps. Whitewash brushes.

Carpenter's stores.

"Propeller" notice boards. "Smoking" notice boards. "No admittance" notice boards. Pump hook, jointed. Chain punches. Pitch pot, 3 gals. and ladle. Tar bucket. Grindstone and trough, 18" diam. Shifting spanner, large. Ring spanners, to fit bunker plates, etc. Keys for cargo ports. " " sidelights. " coal ports. " " mushroom ventilators. Rim spanner for sidelights. Spanners for deep tank hatch bolts. Rail straightener, 3'6" long. Rod sounding rods. Flexible sounding rods, 2' 0" long. Caulking tools. Caulking mallet. Spare hatch wedges. Capstan bars and rack. Monkey wrench. Wheel-house axes, large. Tools in chest, with ship's name on; chest and tools. One 26" hand saw. One crosscut. One auger 11" One purger 14". One adze. One hammer. Two top mawls. Two screwdrivers. One jack plane. One hand plane. Three chisels, assorted. Three gimlets, assorted.

Steaming Lights.

Two masthead Port | lamps, brass, for electric. | do. do. galvanized iron, for oil. Two riding lights | oil. Three ruby lights | oil.

Three black balls.

Spare glasses for lamps, 2 for each.

Carriers and halliards for masthead and riding lights.

Lamps and lanterns.

"Exit" lamps in passengers' quarters.

Dark lanterns (3 for large ships). Cargo lanterns (12 for large ships).

White lanterns (2 for large ships).

Hurricane lights (5 for large ships) with 3 spare glasses.

Lamps for saloon and officers' rooms in small ships.

Lamp scissors. Oil funnels. Lamp wicks.

Rockets, signal cannon, to be supplied as required by U. S. laws, together with owner's night signals, etc.

Navigating Instruments.

Standard compass and stand.
Ten inch spirit compasses in navigating positions.

navigating positions.

One spare card.

Boat's compasses, 4" card.

Sounding machine, or deep sea
lead (28 lbs.), line and
reel. 130 fathoms.

Hand lead (16 lbs.), line, and reel, 30 fathoms.

Pelorus.
Clocks.
Aneroid barometers.
Telescope.
Binoculars, marine.
Log slates.
Parallel ruler.
Pair dividers.
Chart weights.
Foghorn.

Tarpaulins.

Usually 3 to each weather deck hatch; 1 to others.
One rubber sheet to hatches on which cattle are carried.
Covers to all sails and instruments, wheels, etc., in exposed positions; weather cloths to shelter passenger decks in large passenger ships.

Bakery Outfit.

Two biscuit tubes. One biscuit forcer. One apple corer. One bread rasp. One galvanized bucket. One buckwheat jug. Six cake hoops. One hundred and twenty corn bread tins. One dough knife. One scraper. One sugar dredger. One flour dredger. Two flour scoops. One tin opener. One casserole mould. Eighteen (quart) jelly moulds.

Eighteen (quart) jelly moulds. Six pudding moulds with lids. Seventy-two muffin rings. One bread grater. One nutmeg grater. One barm can. One palette knife. Two sets cutlet paste cutters. Six paste brushes. Two rolling pins. One set of scales, $\frac{1}{4}$ oz. to 14 One flour sieve. One spice box complete. Twelve bread tins. Two French roll tins. Twenty-four open tart tins. One hundred and forty-four patty tins. Six rice pudding tins. Six roll tins. Eighteen sandwich bread tins. with lids. Twenty-four cake sponge frames. One water can. Two egg whisks. One set icing pipes. One icing bag. One enameled whisking bowl. One patent egg whisk. One egg basket. One suet machine. One bread knife. Twelve large bread sheets. One bread prover, galvanized iron, $6'0'' \times 2'5'' \times 1'5''$ with copper steam pipe. Galley Outfit. Braising pans, copper, with wire nets. Water cans.

Braising pans, copper, with wire nets.
Water cans.
Butcher's choppers.
Cook's saws.
Tin colanders.
Chopping block.
Dippers, tin.
Aluminum stew pans, with handles and lid.

Sauce pans (enameled iron), 1 qt., 3 pt., and 2 qt. Oval fish kettle and lid. Potato masher. Dog baskets, wicker, tin lined. Sieves, hair mesh. Sieves, wire mesh. Sauce ladles, small. Tin opener. Beef press. Pea soup masher, tammy sieve. Copper stew pans, 6"-16" diam.. with long handles, and lids with long handles. Stock bucket. Stock pot. Omelette pans, copper. Frying pans, round. Frying pans, oval. Tormentors. Pokers. Shovels. Rakes. Gridirons, double. Gridirons, large. Sets of skewers, assorted sizes, Egg basket. Glaze pot, copper and brush. Four-inch basket ladle, wire. Frying baskets, round, wire. Cook's forks. Salt box. Flour box. Wire gravy strainer. Grill tins. Two gallon copper kettle. Jelly bag. Knives, French. Knives, butcher's. Knives, mincing. Knives, oyster. Knives, palette. Knives, potato.

Bill of fare frame.

Pie pans, $8'' \times 6''$.

Pie pans, $12'' \times 8''$, enameled.

Steak tongs. Store tins. Stove top hooks. Porridge whisks, strong wire. Cutlet bat. Vegetable cutters. Vegetable scoops. Brawn moulds. Tongue press. Pepper dredgers. Hot pot tins. Plate carriers. Bread grater. Flour dredge. Iron ladles. Larding needles. Trussing needles. Potato masher. Egg slicer. Fish slicer. Spoons, iron. Spoons, wood. Steel. Ship's Galley Outfit. Mess kids, large, small and oval. Square steamers. One square coffee boiler (28 gal.) B. T. Oval boilers (15 gal.) B. T. Roast tins. Saucepans, iron enameled. One round steam boiler (50

gal.) cast iron with large brass tap.
Range.
Colanders.
Shovel.
Poker.
Buckets, galvanized iron.
Rake.
Tormentor.
Large ladle.
Square duff tins.
Chopping block.

Pantry Outfit.

Pair butter spades. Meat choppers. Poultry choppers. One clock. Dish covers, B. M. Egg slicers. Ice pricker. Jugs (enameled), 1 gallon. Two bread knives. Two carving knives. Two French knives. Two ham knives. Pairs knives and forks for poul try. Plate covers, tin. Iron spoons, 18" long.

try.
Plate covers, tin.
Iron spoons, 18" long.
Lemon squeezer.
Tin openers.
Slop receivers, 20 gallons.
Soup ladles.
Soup tureens, B. T.
Steel.
Waiter's carpathian.

Wire whisks 12"-18".

Milk cans with lid and spout,
2 gallons.

Steam carving table 6'0" × 2'

Steam carving table 6'0" × 2'
6", with tin top, 3 large,
2 medium and 2 small
wells.

Steam egg boiler. Steam bain-marie, 4 stew pans, brass frame. One coffee boiler, 10 gallons,

One hot water boiler, 15 gallons E. P.

Whisking bowl. Water cooler.

Electroplate and Cutlery.

Asparagus tongs. Butter coolers. Cheese scoops. Tea pots, 3 pints. Tea pots, 11 pints. Coffee pots, 2 pints. Coffee pots, 1 pint. Entree dishes, 10" oval. Entree dish covers, with movable handles. Vegetable dishes. Vegetable dish covers, with movable handles. Ice tongs. Sauce frames (Worcestershire, Prs. fish carvers. Fish forks. Fruit forks. Dessert forks. Pickle forks. Butter knives. Fish knives. -Dessert spoons. Soup spoons. Sauce ladles. Soup ladles. Finger bowls. Ice pails. Napkin rings, numbered. Prs. nut crackers. Toast racks, large. Toast racks, small. Fruit knives. Mustard spoons. Salt spoons. Tea spoons. Egg spoons. Table spoons. Sugar bowls, large. bowls, small. tongs, small. tongs, large. Sardine tongs. Cream jugs, large. Cream jugs, small. Fine sugar sifters, gilt bowls. Fine sugar bowls. Syrup jugs, hinged lids.

Hot water jugs, 1 pint.
Tureen and covers for soup, 6
quarts.
Tureen and covers for sauce.
Fruit dishes, gilt, large 12"
long.
Fruit dishes, gilt, small, 9½"long.
Wine corks.
Waiters, 8", 10", 12".
Wine funnel.

Glass.

Celery glasses.

Soda glasses.

Tumblers.

Champagne glasses. Claret glasses. Liqueur glasses. Port and Sherry glasses. Cocktail glasses. Bedroom tumblers. Pickle jars. Glass dishes, small oval. large oval. .. large round. small round. ground glass for ice cream. Water decanters, saloon. Water decanters, bedroom. Salt casters. Pepper casters, E. P. tops. Red pepper casters, E. P. tops.

General Stores.

Spring balance. Scales and weights. Handy billy. Brooms. Brushes, banister. Dustpans and brushes. Shoe brushes. Buckets. Mops. Cuspidores and linings. Dinner bell. Cork screws. Knife board. Table gong. Deck chairs. Wicker chairs. Blotting pads. Bibles, etc. Chess men, etc. Library books. Printing press.

CHAPTER IV.

FREEBOARD.

In the following tables the word Freeboard denotes the height of the side of a ship above the waterline at the middle of her length, measured from the top of the deck at the side, or. in cases where a waterway is fitted, from the curved line of the top of the deck continued through to the side. The freeboards and the corresponding percentages of reserve buoyancy necessary for flush-deck steamers not having spar or awning decks and for flush-deck sailing vessels are given in Tables A and D for vessels of these classes and of various dimensions and proportions. The freeboards necessary for spar- and awning-deck steamers are given in Tables B and C. The latter are determined by considerations of structural strength, and they denote the limitations to depth of loading which are thereby imposed upon first-class vessels of these types. The freeboards and percentages of reserve buoyancy thus obtained being in excess of what would otherwise be required, the amount of such percentages are not given in Tables B and C.

The exact freeboard required for a given ship of standard proportions belonging to either of the classes comprised in Tables A and D may be calculated by constructing a displacement scale to the height of the deck to which the freeboard is measured, so as to give the whole external volume up to the upper surface of that deck. The percentage of the total volume which is given in the tables as the reserve buoyancy for a vessel of given type and dimensions will be the amount of volume that must be left out of the water. If a waterline be drawn up upon the displacement scale aforesaid to cut off the given percentage of total volume, the height of side above this line will

be the freeboard required.

In order to simplify and reduce the work that would be involved by the above mode of determining the waterline and the consequent freeboard that correspond to a given percentage of reserve buoyancy, an approximate method is adopted in the following tables, which enables the freeboard of a vessel to be calculated with a sufficient degree of accuracy for all ordinary working purposes. The use of this method not only saves the time and labor that would be involved by making a complete displacement scale for the whole external volume of the ship but, what is much more important, it makes the tables easily and directly applicable in cases where such a displacement

scale for a vessel is not at hand, or where the data requisite for

constructing one are not procurable.

In this approximate method the form of the ship is taken into account by means of proportionate quantities, which are termed coefficients of fineness, instead of by the exact volumes that a displacement scale would give. It is found that the whole internal volume of a ship as measured for register tonnage divided by the product of the length, breadth, and depth, measured as described in the following clauses, 1, 2, and 3, gives a fractional quantity of coefficient which bears a nearly constant relation to the quantity that would be obtained by dividing the whole external volume below the upper surface of the deck by the product of the length, breadth, and depth. This fractional quantity is called the "coefficient of fineness" for freeboard purposes, and it serves the same practical object, when combined with the dimensions of the ship in the manner explained in the tables, as the volume itself would do.

In applying such an approximate method as the above, it is necessary to connect the coefficients of fineness given in the tables with a standard sheer and round of beam. The standard scales for sheer and round of beam that have been adapted for this purpose are given in Clauses 18 and 19 hereafter. Descriptions are also there given of the corrections that should be made for deviations from these standard amounts.

The freeboards given in the tables are for flush-deck vessels in all cases. Such reductions in freeboard as may be allowed for deck erections of various kinds and sizes in steamers not having spar or awning decks and in sailing vessels are described in paragraphs 11, 12, 13, 14, 15, 16, and 17.

No reduction of freeboard should be allowed on account of deck erections in spar-deck and awning-deck steamers, except in spar-deck vessels in which an allowance may be made for a

long bridge house, see pp. 21 and 22.

Tables A and D give the minimum freeboards for first-class iron and steel vessels, the strength of which is at least equal to the requirements of the 100a class in Lloyd's Register for threedeck and smaller vessels. The freeboard of all other iron and steel vessels, classed or unclassed, should be regulated by the same standard, the increase of freeboard required in each case being determined by the limit at which the stress per square inch upon the material of the hull amidships shall not exceed that of the standard class, of the same proportions, form, and moulded depth, when loaded to the freeboards required by Tables A and D. Tables B and C give the freeboards for vessels built in accordance with, or equal to, the requirements of Lloyd's Register for the spar- and awning-deck classes, and are

subject to the conditions just stated for any modifications of strength in excess of diminution of the requirements of their respective classes.

- 1. LENGTH. The length of the vessel is measured on the load line from the fore side of the stem to the aft side of the stempost in sailing vessels, and to the aft side of the aft post in steamers.
- 2. Breadth. The breadth used in obtaining the coefficient of fineness is the extreme breadth measured to the outside of plank or plating as given on the certificate of the Ship's Registry.
- 3. DEPTH OF HOLD. The depth used in obtaining the coefficient of fineness is the depth of hold as given on the Certificate of the Ship's Registry. This dimension is subject to modification in determining the coefficient of fineness as explained in Clause 4.

4. COEFFICIENT OF FINENESS. — The coefficient of fineness in one-, two-, and three-deck and spar-deck vessels is found by dividing 100 times the gross registered tonnage of the vessel below the upper deck by the product of the length, breadth, and depth of hold. In awning-deck vessels the registered depth and tonnage are taken below the main deck.

(a) It is of importance in the application of the rules and tables of freeboard that the coefficient of fineness deduced from the under-deck tonnage and the principal dimensions to be a correct index to the vessel's relative fullness of form, and that a change in any of those elements which affect the coefficient, determined in accordance with the rule set forth, should be considered, and the necessary correction, having regard to the special circumstances of the case, introduced. Among the cases that have from time to time come under notice are the following:

(b) Vesset Having a Cellular Bottom Throughout, or Floors of Greater Depth than those Usually Fitted. — In such a case the coefficient as determined from the under-deck tonnage is in most instances slightly greater than it would be if the vessel were framed on the ordinary transverse system with floors of the usual depth. No general rule can be given for guidance, but it is not difficult, if the depth and slope of the top of the cellular bottom or floor be compared on the midship section with the depth and slope of an ordinary floor, to determine very closely the amount of the correction necessary.

(c) Vessel Constructed with Floors of the Ordinary Kind, but with a Cellular Bottom for a part of the Length Amidships Under

the Engines and Boilers. — In such case the registered underdeck tonnage is smaller than it would be if the vessel were framed with ordinary floors throughout, the difference being the tonnage of the space between the bottom of the cellular bottom in the part amidships and the level of the ordinary The depth of hold is also measured by the customs officials to the top of the cellular bottom, and this depth is inserted in the register. Under such circumstances, in order to arrive at the coefficient of fineness the vessel would have, if built on the ordinary system throughout and for which the tables are framed, the tonnage of the volume between the top of the cellular bottom and the level of the ordinary floor should be calculated and added to the registered under-deck tonnage. The tonnage so corrected used in conjunction with the depth of hold to the top of the ordinary floor, gives the coefficient to be used in the tables.

(d) Vessel Constructed with a Cellular Bottom Throughout the the Fore and After Holds, but with Floors of the Ordinary Kind Fitted for a Part of the Length Amidships Under the Engines and Boilers. — In such a case the tonnage of the space between the top of the ordinary floors in the part amidships and the top of the cellular bottom, if made continuous, should be estimated and deducted from the registered under-deck tonnage and the remainder employed in conjunction with the depth of hold to the top of the cellular bottom in determining the coefficient of

fineness.

(e) Other cases may in practice arise in which the registered under-deck tonnage, or the registered depth of hold, or registered breadth require modification before being used in the determination of the coefficient of fineness, but little difficulty will be experienced in making the necessary correction if it be remembered that the coefficient sought is the coefficient the vessel

would have if framed on the ordinary transverse system.

5. MOULDED DEPTH. — The moulded depth of an iron or steel vessel, as given in the tables, is the perpendicular depth taken from the top of the upper deck beam at side, at the middle of the length of the vessel, to the top of the keel and the bottom of the frame at the middle line, except in spar- and awning-deck vessels, in which the depth is measured from the top of the main-deck beams. In wooden and composite vessels the moulded depth is taken to be the perpendicular depth from the top of the upper-deck beam at the side of the vessel amidships to the lower edge of the rabbet at the keel.

(a) The form at the lower part of the midship transverse section of many wooden and composite vessels being of a hollow

character, as in cases where thick garboard strakes are fitted, the moulded depth in such instances should be measured from the point where the line of the flat of the bottom continued cuts the keel.

- 6. FREEBOARD. The moulded depth, taken as above described, is that used in the tables for ascertaining the amount of reserve buoyancy and corresponding freeboard in vessels having a wood deck, and the freeboard is measured from the top of the wood deck at side, at the middle of the length of the vessel.
- (a) On the same principle, in flush-deck vessels, other than spar or awning decked, and in vessels fitted with short poop and forecastle, having an iron upper deck, not covered with wood, the usual thickness of a wood deck should be deducted from the moulded depth of the vessel measured as above, and the amount of reserve buoyancy and corresponding freeboard taken from the column in the tables corresponding with this diminished moulded depth: Example. In a steamer fitted with an iron upper deck, not covered with wood, and having a moulded depth of 19 ft. 10 ins., four inches, or the usual thickness of a wood deck, must be deducted from this, leaving a depth of 19 ft. 6 ins. The freeboard of such a vessel with a coefficient of fineness of 0.76, taken from the column under 19 ft. 6 ins., is 3 ft. 8½ ins., which should be measured from the top of the iron upper deck.
- (b) In spar-deck vessels having iron spar decks and in awning-deck vessels having iron main decks, the freeboard required by the tables should be measured as if those decks were wood covered. Also in vessels where ${}_{1}^{7}{}_{0}$, or more, of the main deck is covered by substantial erections, the freeboard found from the tables should be measured amidships from a wood deck, whether the deck be of wood or iron. In applying this principle to vessels having shorter lengths of substantial enclosed erections the reduction in freeboard, in consideration of its being measured from the iron deck, is to be regulated in proportion to the length of the deck covered by such erections. Thus in a vessel having erections covering ${}_{1}^{6}{}_{0}$ of the length, the reduction is ${}_{1}^{6}{}_{0}$ of $3\frac{1}{2}$ inches, or 2 inches.
- 7. For vessels which trim very much by the stern, through the engines being fitted aft, the freeboard, as ascertained from the tables, if set off amidships would not cut off the amount of surplus buoyancy deemed necessary, and in such cases the suitable freeboard amidships could only be determined after full information is obtained regarding the vessel's trim.

8. The following example will illustrate the general application of the tables:

In a steamer of the following dimensions, viz., length, 204 ft.; breadth extreme, 29 ft.; depth of hold, 16.0 ft.; registered tonnage under deck, 628 tons; and moulded depth, 17.0 ft.; the under deck capacity in cubic feet is 68,200; by dividing this by 94,656, that is, the product of the length, breadth, and depth of hold, the quotient is 0.72, or the coefficient of fineness.

If we now refer to Table A at 17.0 ft. moulded depth and trace the line opposite the coefficient 0.72 to the column corresponding with this depth, it is found that the winter freeboard given for a first-class steam vessel without erections, whose length is twelve times the moulded depth, is 2 ft. 11 ins., corresponding with a reserve buoyancy of 25 per cent of the total bulk.

- 9. Vessels of Extreme Proportions. For vessels whose length is greater or less than that of the vessel of the same moulded depth for which the tables are framed, the freeboard should be increased or diminished as specified in the footnote to the tables. Thus, if the vessel in the example clause 8 were 224 ft. long, the winter freeboard required would be 2 ft. 11 ins. plus 2 ins. or 3 ft. 1 in. For steam vessels coming under paragraphs 11 and 12 with enclosed erections extending over $\frac{1}{10}$, or more, of the length of the vessel, the correction for length should be one-half that specified in Tables A.
- 10. Breadth and Depth. In framing the tables it has been assumed that the relation between the breadth and depth is such as to ensure safety at sea with the freeboard assigned when the vessel is laden with homogeneous cargo; for vessels of less relative breadth the freeboard should be so increased as to provide a sufficient range of stability, or other means adopted to secure the same.
- 11. Erections on Deck. For steam vessels with top-gallant forecastles having long poops, or raised quarter-decks connected with bridge-houses, covering in the engine and boiler openings, the latter being entered from the top, and having an efficiently constructed iron bulkhead at the fore end, a deduction may be made from the freeboard given in the tables, according to the following scale:

(a) When the combined length of the poop, or raised quarter-

deck, bridge-house, and top-gallant forecastle is:

100 of the length of the vessel, deduct 90 per cent of the difference between freeboards in Tables A (after correction for sheer) and Tables C.

⁹₁₀ of the length of the vessel, deduct 85 per cent of the difference between freeboards in Tables A (after correction for sheer) and Tables C.

⁸⁵/₁₀₀ of the length of the vessel, deduct 80 per cent of the difference between freeboards in Tables A (after correction for sheer) and Tables C.

⁸/₁₀ of the length of the vessel, deduct 70 per cent of the difference between freeboards in Tables A (after correction for sheer) and Tables C.

 $\frac{7}{10}$ of the length of the vessel, deduct 55 per cent of the difference between freeboards in Tables A (after correction for sheer) and Tables C.

 $\frac{7}{10}$ of the length of the vessel, deduct 40 per cent of the difference between freeboards in Tables A (after correction for sheer) and Tables C.

When the engine and boiler openings are protected only by a long raised quarter-deck, a less reduction in freeboard will be allowed.

(b) For intermediate lengths of erections the amount of the reduction in freeboard should be ascertained by interpolation.

(c) The above scale of allowance is prepared for vessels having long poops or raised quarter-decks 3 ft. high for vessels having a length of 100 ft., 4 ft. high at a length of 250 ft., and 6 ft. high at a length of 400 ft. and upwards. Intermediate lengths in proportion. For raised quarter-decks of less height the length allowed is to be in proportion to the standard of height.

(d) It is to be understood in the application of this scale of allowance for erections on deck to vessels with long poops or with raised quarter-decks and bridge-houses combined, that the deduction is a maximum deduction, applicable only to vessels of these types in which the erections are of a most substantial character, the deck openings most effectually protected, and the crew are either berthed in the bridge-house, or the arrangements to enable them to get backwards and forwards from their quarters are of a satisfactory character. For other vessels of the same class the amount of the deduction should be fixed only after a careful survey. Also such vessels when employed in the Atlantic trade will require to have specially provided greater freeboard than that given in the tables.

(e) A sufficient number of clearing ports, as large as practicable and with shutters properly hung, should be formed in the bulwarks of these vessels, between the forecastle and the bridge-house for the purpose of speedily clearing this part of the deck of water.

12. When the erections on a vessel consist of a top-gallan forecastle, a short poop having an efficient bulkhead, an bridge-house disconnected, the latter in steamers covering th engine and boiler openings and being efficiently enclosed wit an iron bulkhead at each end, a deduction may be made fror the freeboard given in the tables according to the followin scale:

(a) When the combined length of the erection is:

 $\frac{9.5}{100}$ of the length of the vessel, deduct 75 per cent of the difference between freeboards in Tables A (after correction fc sheer) and Tables C.

 $\frac{90}{100}$ of the length of the vessel, deduct 70 per cent of th difference between freeboards in Tables A (after correction fc

sheer) and Tables C.

 $\frac{100}{100}$ of the length of the vessel, deduct 60 per cent of th difference between the freeboards in Tables A (after correction

for sheer) and Tables C.

 $\frac{705}{105}$ of the length of the vessel, deduct 50 per cent of th difference between the freeboards in Tables A (after correctio for sheer) and Tables C.

 $\frac{60}{100}$ of the length of the vessel, deduct 40 per cent of th difference between the freeboards in Tables A (after correction

for sheer) and Tables C.

- 100 of the length of the vessel, deduct 32 per cent of the difference between the freeboards in Tables A (after correction for sheer and length) and Tables C (after correction for length)
- 13. When the erections on a vessel consist of a top-gallar forecastle and bridge-house only, the latter in steamers covering the engine and boiler openings and being efficiently enclose with an iron bulkhead at each end, a deduction may be mad from the freeboard given in the tables according to the following scale:

(a) When the combined length of the erections is:

to of the length of the vessel, deduct 30 per cent of the difference between the freeboards in Tables A (after correction for sheer and length) and Tables C (after correction for length)

⁴⁰ of the length of the vessel, deduct 24 per cent of the difference between the freeboards in Tables A (after correction for sheer and length) and Tables C (after correction for length).

¹/₁₀ of the length of the vessel, deduct 10 per cent of the difference between the freeboards in Tables A (after correction for sheer and length) and Tables C (after correction for length).

14. When the erections on a steam vessel consist of a shopoop or raised quarter-deck of a height not less than that laidown in paragraph 11 and top-gallant forecastle only, the

former being enclosed at the fore end with an efficient bulkhead, and when the engine and boiler openings are entirely covered either by the poop or raised quarter-deck or by a strong iron or steel deck-house enclosing the machinery casings, a deduction may be made from the freeboard given in the tables according to the following scale:

When the combined length of the erection is:

‡ of the length of the vessel, deduct 32 per cent of the difference between the freeboards in Table A (after correction for length) and Table C (after correction for length).

I of the length of the vessel, deduct 24 per cent of the difference between the freeboards in Table A (after correction for

length) and Table C (after correction for length).

i of the length of the vessel, deduct 16 per cent of the difference between the freeboards in Table A (after correction for length) and Table C (after correction for length).

i of the length of the vessel, deduct 8 per cent of the difference between the freeboards in Table A (after correction for

length) and Table C (after correction for length).

For erections which cover less than $\frac{1}{6}$ of the length of the vessel, the allowance should be in proportion to that for $\frac{1}{6}$ covered. When, however, the engine and boiler openings are not entirely covered by the poop or quarter-deck or by a strong iron or steel deck-house, the allowance for erections should be $\frac{1}{16}$ of that provided by the foregoing scale.

15. When a steam vessel is fitted with a top-gallant forecastle only, the reduction of freeboard is to be in accordance with the preceding paragraph for a poop not covering the engine and boiler openings and a forecastle of the same combined length.

When there is a short poop only, or a raised quarter-deck of a height not less than that laid down in paragraph 11, enclosed at the forward end with an efficient bulkhead and covering the engine and boiler openings, the deduction from the freeboard is to be half the allowance that is given for a poop or quarter-deck of the same character and a forecastle having the same combined length. When the poop or raised quarter-deck does not cover the engine and boiler openings for the foregoing allowance is to be given.

16. When the erections on a sailing vessel consist of a short poop and top-gallant forecastle only, the former enclosed at the fore-end with an efficient bulkhead, the deduction from the free-board given in the tables should be according to the following scale:

When the combined length of the erection is:

t of the length of the vessel, deduct 10 per cent of the reserve

7

buoyancy, or 12 per cent of the freeboard required for the flush-decked vessel after correction for length;

³/₈ of the length of the vessel, deduct 8 per cent of the reserve buoyancy, or 10 per cent of the freeboard required for the vessel flush-decked after correction for length;

²/₈ of the length of the vessel, deduct 6 per cent of the reserve buoyancy, or 8 per cent of the freeboard required for the vessel

flush-decked after correction for length:

\(\frac{1}{6}\) of the length of the vessel, deduct \(\frac{4}{2}\) per cent of the reserve buoyancy, or 6 per cent of the freeboard required for the flush-decked vessel after correction for length. In cases where less than \(\frac{1}{6}\) of the length of the vessel is covered by erections, the allowance should be in proportion to that given for erections covering \(\frac{1}{6}\) of the length.

17. When a sailing vessel is fitted with a top-gallant forecastle only, the reduction in reserve buoyancy should be one-half that prescribed by the previous paragraph for the case where, in addition to the forecastle, the vessel is fitted with a poop of the same length.

When there is a poop only, the allowance is to be half of that which in this paragraph is given for a forecastle only of the

same length.

18. Sheer. — The tables are framed for vessels having a mean sheer of deck measured at the side, as shown in the following table:

	LENGTH OVER WHICH SHEER IS MEASURED.							
	100	150	200	250	300	350	400	
	Mean Sheer in Inches Over the Length Specified.							
Flush-deck Vessels.—Sheer to be measured abreast stem and sternpost.	ssels.—Sheer to be abreast stem and short poops and fore-teer to be measured istant \(\frac{1}{5} \) the length from each end							
Vessels having short poops and fore- castles.—Sheer to be measured at points distant ½ the length of the vessel from each end	14	18	22	26	30	34	38	
Vessels having short forecastles only.—Sheer to be measured abreast the sternpost and at a point distant \(\frac{1}{8} \) the length from the stem.	141	181	23	27	31	35½	40	

(a) In flush-deck vessels and in vessels to which paras. 11 and 12 apply, when the sheer of deck is greater or less than the above and is of a gradual character, divide the difference in inches between it and the mean sheer provided for by 4 and the result in inches is the amount by which the freeboard amidships should be diminished or increased according as the sheer is greater or less.

(b) In vessels having short poops and forecastles, and in those having short forecastles only, the freeboard should be corrected in respect of the excess or deficiency in reserve buoyancy due to variations in sheer from the standard amount over the length uncovered by substantial erections, as provided in the above table. One-fourth the difference between the mean sheer specified and that measured as described is approximately the amount by which the freeboard should be modified in respect of sheer.

(c) The divisor 4 is to be used when the sheer is of a gradual character, and is not strictly applicable either to those cases in which the sheer is suddenly increased at the bow or stern, or to those in which it does not maintain its normal rate of increase

to the ends of the vessel.

(d) In all cases the rise in sheer forward and aft is measured with reference to the deck at the middle of the length, and where the lowest point of the sheer is abaft the middle of the length, one-half the difference between the sheer amidships and the lowest point should be added to the freeboard specified in the tables for flush-deck vessels and for vessels having short poops and forecastles only.

(e) Where, as in some instances, vessels fitted with long poops or raised quarter-decks connected with bridge-houses have the deck line rising rapidly from amidships to the front of the bridge, and from that point onwards gradually approaching the normal sheer line, the freeboard may be slightly modified in consider-

ation of the increase of height of deck in the "well."

(f) In flush-deck vessels and in vessels having short poops and forecastles the excess of sheer for which an allowance is made shall not exceed one-half the total standard mean sheer for the size of the ship.

(g) No decrease should be made in the freeboard of spar- and

awning-deck vessels, in respect of excess of sheer.

19. ROUND OF BEAM. — In calculating the reserve of buoyancy an allowance has been made of one-quarter of an inch for every foot of the length of the midship beam for the round up. When the round of the beam in flush-decked vessels is greater than given by this rule divide the difference in inches by 2 and diminish or increase the freeboard by this amount. For vessels with erections on deck the amount of the allowance

should depend on the extent of the main deck uncovered. This rule for round of beam does not apply to spar- or awning-deck vessels.

20. As a general illustration of the way in which the tables should be used in modifying the freeboard on account of erections on deck, extreme proportions and variations in sheer, the following may be taken as an example.

A vessel is 234 ft. long, 29 ft. broad, and has a moulded depth of 17.0 ft., the coefficient of fineness being .72. Suppose the vessel to have a poop and bridge-house of the united length of 121 ft., and a forecastle 20 ft. in length, and let the sheer forward, measured at the side, be 4 ft. 6 ins., and aft, 2 ft. 1 in.

Freeboard by Tables A if of the normal	Ft.	In.
length, without erections, and with the normal amount of sheer	2	11
less than that in the vessel, and the re-	0_	11/2
39½ ins. mean sheer	0	$\frac{9\frac{1}{2}}{9\frac{1}{2}}$
Difference	2	0

The combined length of the erections is $\frac{1}{2}\frac{4}{3}\frac{1}{4}$ or $\frac{4}{10}$ of the length of the vessel, and the allowance for erections under clause 11 will be therefore $\frac{4}{10}$ of 24 ins., or $9\frac{1}{2}$ ins.

We have therefore:

Amount deducted from freeboard for excess of sheer	in. 1½ 9½ 2 13
The length being 30 ft. in excess of that for which the tables are framed, the addition to the freeboard in respect of the same is one-half of § 6 of 1.1 in., or	11/2

That is $11\frac{1}{2}$ ins. to be deducted from 2 ft. 11 ins., leaving a winter freeboard of 1 ft. $11\frac{1}{2}$ in.

111

Corresponding summer freeboard, 1 ft. 9 ins.

21. Vessels loaded in fresh water may have less freeboard than that given in the several tables according to the following scale:

				REDUC	REDUCTION IN FREEBOARD.					
	Mo	OLDED	DEPTH IN FEET.	Vessels Without Erections on Deck.	Awning- deck Vessels.	Spar- deck Vessels.				
				Ins.	Ins.	Ins.				
			er 8	$1\frac{1}{2}$

16	"	"	19	. 31/2	4	41				
19	"	"	22	4		5				
22	"	"	25		$\frac{4\frac{1}{2}}{5}$	51				
25	"	"	28	52	$5\frac{1}{2}$	$ \begin{array}{c c} 4\frac{1}{2} \\ 5 \\ \hline 5\frac{1}{2} \\ 6 \end{array} $				
28	"	"	31		62	$6\frac{1}{2}$				
31	"	"	34	6	$\frac{61}{2}$	72				

MEMO.—The weight of a cubic foot of salt water is taken, in the above table, to be 64 lbs., and that of fresh water 62.5 lbs.

- 22. The freeboards assigned by the following tables are not intended to apply to vessels when navigating inland waters or rivers, and when a stretch of such water has to be traversed such deeper loading will be permissible as may be due to the weight of fuel required for consumption between the points of departure and the open sea.
- 23. The freeboards of vessels having ports, scuppers, or other openings in their sides is to be regulated by the following considerations. When the openings are in the nature of watertight ports for cargo, coals, etc., and are therefore not intended to be opened except in harbor, no modification of the freeboard as determined by the foregoing tables will be necessary, provided the covers of the openings are sufficiently strong and are efficiently secured. In the case, however, of vessels having scuppers through the sides from a 'tween deck space below the upper deck or side scuttles or other openings of a similar nature, when the freeboard as determined by the foregoing tables does not provide a sufficient height from the load-line to the sills of the side scuttles, or to the deck which is drained by the scuppers, the freeboard is to be increased; and the amount of the increase,

if any, is to depend on the nature of such openings and on the means adopted for closing them. In the case of hinged side scuttles of the usual pattern, when the glass is of sufficient thickness and the scuttles are efficiently secured by metal bolt and nuts, and hinged watertight iron shutters of deadlights are provided on the inside of the glass, the loadline as determine by the centre of the disc or by the Indian summer line, if a marked, is to be not less than 6 inches below the sill of the lowest side-scuttle.

24. The freeboards required by the foregoing tables are t be assigned on the condition that the engine and boiler casing above the upper deck are of sufficient height and strength with suitable means provided for closing all openings in ther in bad weather, and the weather deck hatchways are properl framed with substantial coamings, and strong hatch cover the latter being efficiently supported by shifting beams an fore-and-afters suitable to the dimensions of the hatchway When these conditions are not complied with the freeboar

may require to be increased, regard being given, however, the trade in which the vessel is intended to be employed.

25. In no case shall the deepest loadline in salt water, whether

25. In no case shall the deepest loadline in salt water, whethe indicating the summer or Indian summer line, be assigned at higher position than the intersection of the top of the upper deck with the vessel's side, at the lowest part of the deck.

In the case of shelter-decked vessels the deck next below the shelter deck is to be regarded as the upper deck.

Memorandum of Explanatory Notes on the Applicatio of the Tables of Freeboard, Drawn Up with a View to Securing Uniformity of Practice on the Part of Those Entrusted with the Assignment of Freeboard

Deck Line. — In the case of vessels with uncovered iron of steel decks, a width of gutter waterway is to be assumed, and the point so obtained levelled out to the vessel's side. In the case of vessels of 24 feet beam and under, the width of the waterway assumed should be 12 inches, and in vessels of 42 fee and above, 21 inches. In vessels of between 24 and 42 fee beam the width of the gutter waterway is to be taken as ha an inch for every foot in beam.

Where a wood deck maintains a uniform thickness to the side

of a vessel, the same method should be adopted.

In cases where an iron deck is partly covered with wood, the deck-line is to correspond with the top of the deck amidship.

whether the deck at that part be of wood or of iron, and the necessary corrections should be made in accordance with paragraph 6, as also the correction always required to the statutory deck-line.

Bridge-house in Spar-decked Ships.—In a spar-decked ship, where an efficient bridge-house is fitted amidships, covering the engine and boiler openings, if it extends over at least two-fifths of the vessel's length and has scantlings not less than the requirements of Lloyd's Rules (1885) for bridge-houses, it is to be taken into consideration in estimating the strength of the vessel for freeboard.

If the scantlings of the bridge-house are equal to the requirements of Lloyd's Rules (1885) the allowance on this account

should not exceed that given in the following table:

Moulded Depth of Vessel to Main-deck.	Allowance.
Feet. 20. 24. 28.	Inches. 4 3 2 1

If, however, the scantlings of the bridge-house are in excess of Lloyd's Rules (1885) the freeboard is to be determined on the basis of a comparison between the strength of the actual vessel and the strength of a vessel of the same dimensions, built to the three-decked rule, and of a vessel built to the spardeck rule, including a bridge-house in each case.

Tables of Freeboard.—Additional freeboard will be required in the case of vessels classed 90A and 80A, or in vessels of equivalent strength thereto in accordance with the following scale:

Length of vessel:

FEET.	150	175	200	225	250	275	300
90A additions	In. 1/2 1	In. 1/2	Ins. 1/2 11/4	Ins. $\frac{3}{4}$ $1\frac{1}{2}$	Ins. 34 134	Ins. 1 2	Ins. 11/4 21/2

Wherever in these explanatory notes reference is made to classes of vessels of Lloyd's various types, it is to be under-

stood that these apply equally to all other vessels of equivale strength, whether classed by other classifying associatio such, for instance, as the Bureau Veritas or the British C

poration, or unclassed.

If the frame spacing be increased one-fourth, the thickness all the shell-plating, excepting garboard and sheer strak should be increased by one-twentieth of an inch over the thic ness required in the standard ship. Other increases in spaci should be dealt with in the same proportion.

PARA. 1—LENGTH.—The length of erection is to be measur with reference to the length of the vessel on the load-line, i. any portion of the erections forward of the fore side of the ste on the load-line, or abaft the after side of the after post on t load-line, is not to be measured for deductions.

PARA. 3 — DEPTH OF HOLD. — The depth of hold as used the computation for ascertaining the coefficient of fineness iron and steel sailing vessels is to be measured to the top of t

ceiling, and in steam vessels to the top of the floors.

The cases of vessels having either an excess or a deficiency mean sheer, as compared with the standard sheer, the register depth to be used for ascertaining the coefficient of fineness is be increased for excess of sheer, or reduced for the deficiency sheer, by one-third of the difference between the standa mean sheer and the vessel's actual mean sheer, after being I duced to the gradual character, if necessary.

PARA. 4 — COEFFICIENT OF FINENESS. — No alteration is be made in the freeboard in consequence of the coefficient fineness being either smaller or greater than those given on t page of the tables from which the ship's freeboard is taken.

PARA. 5 — MOULDED DEPTH. — In cases where a wood deof extra thickness is fitted, or where a wood deck is double throughout, the moulded depth should be increased by the cess of thickness. The freeboard should then be set off from the top of the deck of increased thickness at the side of the vessel.

PARA. 6 — FREEBOARD. — In case of the freeboard bein ascertained by an actual calculation of the reserve buoyanc the drawing used in such calculation should be verified actual measurements at the ship, and such drawing and calculations forwarded to the Board of Trade, and, whatever the result of the calculation, the freeboard assigned should not be less than would be obtained by taking from the tables the freeboard corresponding to the smallest coefficient for a vessel the same moulded depth, except in sailing vessels with largeries of floor (see page 26).

Freeboard as ascertained by these tables is to be measured to the intersection of the deck with the side of the vessel, but in granting certificates of freeboard this must always be corrected so as to state the freeboard amidships when measured to the deck-line, marked in accordance with the statute.

SUB-PARAS. (A) AND (B). — For vessels having iron upperdecks not covered with wood, the allowance is to be made under sub-para. (a), when the erections extend over less than $\frac{1}{10}$ of the length; but in all vessels when the erections cover $\frac{1}{10}$ or more of the length, and in spar- and awning-decked vessels the allowance is to be made under sub-para (b).

Sub-para. (b.) — (b.) — In spar-decked vessels having iron spar decks and in awning-decked vessels having iron main decks, the freeboard by the tables should be calculated, as if those decks were wood-covered, i.e., the ordinary thickness of a wood deck, less the thickness of the stringer plate, should be deducted from the freeboard, also in vessels where 70 or more of the main deck is covered by substantial enclosed erections, the freeboard found from the tables should be measured amidships from a wood deck, or, if the deck is of iron, it should be measured from the iron deck, and the ordinary thickness of a wooded deck required for that size of ship, less the thickness of the stringer plate, should in that case be deducted from the freeboard. In vessels which have $\frac{6}{10}$ of the deck covered, $\frac{6}{10}$ the thickness of a wood deck, less the thickness of the stringer plate is to be deducted from the freeboard. Between $\frac{1}{10}$ and $\frac{1}{10}$ a proportionate quantity; for example, for $\frac{6}{100}$ covered allow $\frac{1}{10}$ the thickness of the deck, after deducting the thickness of the stringer plate. The remainder of the paragraph should be read as printed. N.B. — When the deductions referred to in this sub-para. (b) are allowed the moulded depth is not to be reduced as per subpara. (a) para. 6.

Para. 9. — In the case of vessels coming under para. 12 and having the deck erections not entirely enclosed, the effective length of the open portions is to be assessed as described in paras. 13, 14 and 15; if the length of the enclosed erections plus the length of the open portions, where assessed as above, is at all under $\frac{4}{10}$ of the vessel's length, the entire correction for length is to be applied.

Para. 11.— This paragraph does not apply to vessels in which the effective length of the erections is less than $\frac{6}{10}$ of the length, except in cases where the effective length of the after erection is at least $\frac{4}{10}$ of the length, and the total effective length of the erections is between $\frac{5}{10}$ and $\frac{6}{10}$ of the length of the vessel.

In such cases the allowance should be proportioned betwee that allowed for erections $\frac{1}{10}$ the length under para. 14 and the allowed for erections covering $\frac{1}{10}$ of the length under para and the corrections for length and sheer should be included estimating this allowance. In all other cases of vessels we erections covering less than $\frac{1}{10}$ of the length, para. 14 is to used.

In the case of vessels having erections which are partly op or are less than the standard height the effective length of t

erections is to be computed as directed elsewhere.

No allowance is to be made for a monkey forecastle which less in height than the main or top-gallant rail, or 4 feet, whice ever is the least; where this condition is satisfied, or the for castle is a sunk one having an efficient bulkhead at its afrend, the length to be used in estimating the allowance is to obtained by multiplying the length of the monkey forecast by its height and dividing by 6 feet, the minimum height of top-gallant forecastle. This rule, as well as that relating to the teights of raised quarter-decks, applies to vessels coming uncaras. 12, 13, 14, and 15, as well as under para. 11. In case vessels having no forecastle but in other respects coming under this paragraph, the allowance for erections should be es mated on the supposition that there is a forecastle of \frac{1}{8} then the tessel, deducting from this twice the allowan which the vessel would have for such a forecastle under para.

SUB-PARA. (a). — The difference will not be affected by correction for length, as the allowance will be practically the sar in both tables.

SUB-PARA. (c). — The engine and boiler openings, if preceded only by a raised quarter-deck, will require an addition freeboard varying from 1 inch in vessels of 15 feet mould depth to 2 inches in vessels of 20 feet moulded depth. In vessels having less than 15 feet moulded depth a proportional addition should be made.

If with a small bridge-house in front of, but not covering t

openings, an addition of half the above amount.

SUB-PARA. (d). — If the crew are not berthed in the bridg house, and the arrangements to enable them to get backwar and forwards from their quarters are not satisfactory, an a dition should be made to the freeboard of 1 per cent of t moulded depth of the ship in the case of vessels 180 feet more in length and having wells 70 feet or less in length. the vessel's length does not exceed 150 feet, or if the well is feet or more in length, the foregoing addition will not be r quired. In the case of vessels between 150 and 180 feet

length, or having wells between 70 and 80 feet in length, the addition is to be found by interpolation.

Planks secured in position by lashings are not to be regarded as satisfactory arrangements; and a gangway providing access between the bridge-house and forecastle cannot be considered satisfactory, unless the following requirements at least are complied with:

The gangway to be not less than 18 inches wide and to be efficiently supported at suitable intervals. The ends to be strongly bolted to lugs riveted to the bulkheads of bridge and forecastle, or to the hatch coamings, or to iron standards bolted to the deck or to be secured in some equally efficient manner.

The top of the gangway to be not less than 2 feet 6 inches above the top of the deck at any part. A life-line or rail to be fitted for the entire length of the gangway and to be supported by wrought-iron stanchions suitably spaced and not less than 2 feet 6 inches in height.

If the hatchways are at least 2 feet 6 inches in height the gangway may be fitted between the hatchways and beyond them only, provided that a continuous platform of at least the required height is obtained, and the rail or life-line is fitted and efficiently supported by wrought-iron stanchions for the entire distance including the hatchways. The gangway should be fitted as far inboard as practicable.

SUB-PARA. (e). — The minimum freeing port area is to be as follows:

Length of Bul-	FREEING PORT AREA
warks in	ON EACH SIDE IN
"Well," in Feet.	SQUARE FEET.
5 10 15 20 25 30 35 40 45 50	4.5 6.5 7.5 8.5 9. 9.5 10. 10.5 11.
55	12.
60	12.5

65 and above, 1 square foot to each 5 feet length of bulwark.

If the freeing port area is less than that stated above, an addition is to be made to the freeboard of 1 per cent of the

moulded depth.

The scale of allowance for erections on deck to vessels with top-gallant forecastles having long poops or raised quarter-decks connected with bridge-houses is not to be used without modification, unless the strength of the bulkhead at the front of the poop or bridge-house is at least equivalent to the following requirements:

(a) Poop or bridge bulkheads to be of the thickness of their side plating as required below for vessels under 13 depths to length, with coaming plates $\frac{1}{10}$ of an inch thicker, and to be stiffened with bulb angle according to the following scale, spaced 30 inches apart, and connected to the coaming plates and to the deck plating, or to an athwartship plate on the beams both below and above, with a bracket plate to each end of the stiffener.

Breadth of Ship	Size of Stiffener.	BREADTH OF SHIP.	Size of Stiffener.
24 30 36 42	$\begin{array}{c} 5 \times 3 \times \frac{8}{20} \\ 6 \times 3 \times \frac{9}{20} \\ 7 \times 3 \times \frac{1}{20} \\ 7 \times 3 \times \frac{1}{20} \end{array}$	46 50 54 58 and above	$\begin{array}{c} 7\frac{1}{2} \times 3\frac{1}{2} \times \frac{1}{2}\frac{1}{6} \\ 8 \times 3\frac{1}{2} \times \frac{1}{2}\frac{1}{6} \\ 8\frac{1}{2} \times 3\frac{1}{2} \times \frac{1}{2}\frac{1}{6} \\ 9 \times 3\frac{1}{2} \times \frac{1}{2}\frac{1}{6} \end{array}$

Intermediate sizes to be found by interpolation.

(b) Horizontal brackets or gusset plates of the same thickness as the coamings to be fitted, connecting the poop or bridge bulkheads with the bulwarks on each side of the vessel at about the height of the rail. In the case of vessels having a forecastle and raised quarter deck only, the break bulkhead should be the same thickness as required for bridge sides and stiffened with angles 30 inches apart and of the size required for the main frames.

In order to obtain the allowance for deck erections provided by this paragraph, the openings, if any, in the bulkhead at the front of the long poop or bridge house, must be provided with hinged iron or steel doors, or with some equally permanent means of closing such openings. When the width of the openings exceeds 30 inches, special means are to be provided for maintaining the strength of the hinged doors.

The standard of thickness of the side plating of long poops and bridge-houses is that required by Section 44 of Lloyd's Rules, as modified by the Table of Thicknesses of Side Plating

of Awning-decked Vessels, given in these tables.

The additional freeboard for North Atlantic winter is to be as follows:

ADDITIONAL FREEBOARD FOR WINTER, NORTH ATLANTIC, FOR WELL-DECK VESSELS.

Length of	Рвого	Proportions of Length of Vessel Over Which Erections Extend											
VESSELS	100	65 100	7.0 100	7.5 100	100								
Ft. 180 220 260 300	Ins. 4 3½ 3½ 3½ 3	Ins. 31/2 31/2 3	Ins. 3 3 2 ¹ / ₂ 2 ¹ / ₂	Ins. 2½ 2½ 2 2 2	Ins. 2 2 2 2								

PARA 12.—For vessels having no forecastle, but with the other deck erections prescribed in this paragraph, estimate the allowance for erections supposing there is a forecastle \(\frac{1}{2}\) the length of the vessel, and deduct 1\(\frac{1}{2}\) times the allowance that would be made under para. 15 if the vessel were fitted with such a forecastle only.

This rule also applies to vessels having no forecastle, but with a bridge-house, as provided for in para. 13.

In steam vessels coming under this paragraph, and having closed erections extending over formore of the vessel's length, one-half the length correction specified in Table A is to be made, and the freeboard corrected for sheer only in estimating the allowance for erections, as the allowance for length will be practically the same in both Tables.

For erections which extend over less than $\frac{4}{10}$ the length of the ship, the allowance is to be in proportion.

For instance, if $\frac{3}{10}$ are covered, allow $\frac{3}{2}$ of 25 per cent.

In the case of vessels under 15 ft. moulded depth, in which the combined length of enclosed erections exceeds $\frac{1}{10}$ of the vessel's length, or in which the combined length of erections enclosed and open is equivalent to more than $\frac{1}{10}$ the vessel's length, sub-paras. (d) and (e) of the preceding paragraph are to apply; but the full addition of one per cent of the moulded depth, under each of these sub-paragraphs, is to be made only when the erections cover $\frac{1}{10}$ or more of the length; for lengths of erections intermediate between $\frac{1}{10}$ and $\frac{1}{10}$, the required addition is to be in proportion; thus, when $\frac{1}{100}$ of the vessel's length is covered, the addition to the freeboard is to be $\frac{1}{2}$ per cent of the moulded depth under each sub-paragraph.

Paras. 12 and 13.— The allowance in a sailing ship for a bridge-house in addition to a poop or forecastle, or in addition to a forecastle only, is obtained by the rules laid down in paras. 12 and 13, as the case may be, and is calculated upon the difference between the freeboards of Tables A and C; in other words, the allowance for a forecastle, bridge-house, and poop, or for a forecastle and bridge-house in a sailing ship, is the same as would be given for similar erections in a steamer of the same dimensions.

PARA. 13. — When the combined length of the top-gallant forecastle and bridge-house is $\frac{5}{10}$ of the length of the ship, a deduction from the freeboard may be made of $\frac{5}{100}$, and this is the maximum deduction for this type of vessel.

For erections which extend over less than $\frac{3}{10}$ of the length of

the ship the allowance is to be in proportion.

may be the greatest.

For instance, $\frac{9}{10}$ covered allow $\frac{2}{3}$ of 19 per cent. In all the rules governing the deductions to be made from the freeboard it is to be understood as follows: When the top-gallant forecastle is not closed by an efficient bulkhead at the after end the length is never to be estimated at a greater full value than $\frac{1}{3}$ the length of the ship, but any extension beyond this may be estimated at one-half the value. For instance, if a vessel 240 feet long has an open forecastle 80 feet long, its value for deductions is 30+25=55 feet. When the top-gallant forecastle has an efficient bulkhead with an elongation abaft that bulkhead not enclosed at the after end, the full value of the closed-in portion is to be estimated either as $\frac{1}{3}$ the length of the ship, or the entire length of the enclosed portion, whichever

Open-bridge House. — When the bridge-house extends from side to side of the ship its value for deductions must be considered on its merits, which will depend upon the security of all deck openings, doors, bunker lids or otherwise.

Where these are all properly protected and the bridge-house is open at both ends, one-half the length may be estimated as the value for deductions. Where in addition the fore end is enclosed by an efficient bulkhead \(\frac{3}{4}\) the length may be estimated as the value for deductions.

If the openings in the bulkhead at the after end of a bridge erection, having its fore end closed, are efficiently protected by weather boards properly fitted to at least half the height of the erection, the full length of the erection may be allowed in estimating its value for freeboard. This does not apply, however, to the case of a long erection falling to be dealt with under paragraph 11, as in well-decked vessels having the well aft,

except in shelter-decked vessels having efficient means provided for temporarily closing the openings in the shelter-deck in had weather.

In the case of steamers coming under paragraphs 12 and 13, when the engine and boiler openings are not covered by an erection extending from side to side, bridge-houses may have an allowance not exceeding that which would be given for half the length of a bridge-house of the same character covering engines and boilers.

Paras. 14 and 15. — When the poop has no efficient bulkhead, or the bulkhead does not extend across the vessel, one-half its length may be allowed, provided always proper freeing ports are fitted.

When the openings in the bulkhead are provided with efficient weather boards or other efficient temporary means of closing, and extending the full height of the openings, then the full

length of the poop may be allowed.

In no case, however, shall shifting boards or any other temporary means of closing the openings in the bulkheads at the after end of a bridge-house, or fore end of a poop be considered satisfactory, unless the means of their attachment, whether by channels, hooks, cleats, or otherwise, are permanently secured to the bulkheads.

The standard heights of forecastles and raised quarter-decks, as defined in para. 11, pages 6 and 16, apply also to these

paragraphs.

PARAS. 16 and 17.—In the case of a sailing vessel having a forecastle and raised quarter-deck, or a raised quarter-deck only, the latter of less than 4 feet in height, the length of raised quarter-deck to be allowed should be in proportion to its height as compared with the standard height of 4 feet.

The provisions of the preceding paragraphs relating to the height of forecastles, bulkheads at the after end of forecastles and at the fore end of poops, and the means of closing openings in poop bulkheads, are also to be applied to sailing vessels dealt

with under paras. 16 and 17.

"PARA. 18. SHEER. — Sheer of a gradual character is to be

defined as follows: —

"At \(\frac{1}{3}\) the length of the vessel from the stem or sternpost the sheer is to be 55 per cent of the sheer at stem or sternpost; at \(\frac{1}{3}\) the length from stem to sternpost 26 per cent, and at \(\frac{3}{3}\) the length 7 per cent.

"In those cases in which the sheer is required to be taken at the stem and sternpost and the sheer is found to be not of the grad-

ual character, the following method of computing the effective mean sheer is to be used: -

"Let S = mean of the actual sheers at stem and sternpost;

"Let $S_1 =$ mean of sheers at $\frac{1}{6}$ length from stem and sternpost ÷ .55.

"If S is greater than S₁ the effective mean sheer to be used in the computation of freeboard is S_1 .

"If S is less than S_1 the effective mean sheer to be used is $\frac{S+S_1}{2}$

"In those cases in which the sheer is required to be taken at } of the vessel's length from stem or from sternpost the sheer as actually measured at the prescribed point may be used in ordinary cases without any correction on account of a departure of the sheer line from the gradual character.

"When correcting the depth of hold for excess or deficiency of sheer (paragraph 3, page 23), the mean of the sheers at 1 of vessel's length from stem and from sternpost divided by .58 should in all cases be taken as the vessel's actual sheer for this

purpose.

In cases where there is no forecastle the sheer is to be measured at the stem and sternpost, and corrections made for it ir

all respects as in the case of flush-decked vessels.

When the bridge-house is enclosed, the sheer should be taker at the stem and sternpost and the freeboard corrected for sheer in estimating the allowance for erections. When the bridge house is not enclosed at both ends, the sheer should be measured as if there were no bridge-house, and the freeboard should or should not be corrected for sheer in estimating the allowance for erections, according as the sheer is measured at the stem of at 1 length from the stem.

SUB-PARA. (a). — Surveyors should note that paras. 11 and 12 apply either to vessels of the ordinary well-decked type or to vessels having a poop and forecastle with a disconnected bridgehouse.

Sub-para. (d). — The extent of the depressed part of the sheer covered by deck erections is to be allowed for in applying this rule.

Sub-para. (e). — In vessels obtaining an allowance for deck erections under para. 11 and having considerably less than the normal sheer, the freeboard should be modified in consideration of the decrease of height of deck in the "well."

Sub-para. (f). — In flush-deck vessels the total standard means the sheer measured at the stem and sternpost. In vessels having poops and forecastles, it means the sheer measured at points distant $\frac{1}{6}$ of the vessel's length from stem and stern-

post.

In vessels obtaining an allowance for deck erections under para. 11, where the sheer drops abaft amidships, the height of the raised quarter-deck is to be taken from the level of the top of the midship beam.

PARA. 19 — ROUND OF BEAM. — In flush-deck sailing vessels the excess of round of beam for which an allowance is made shall not exceed the standard round of beam; and for sailing vessels having erections on deck the allowance shall be further reduced in proportion to the extent of the main deck uncovered.

Table A.

The deductions for summer in vessels having deck erections is to be intermediate between those required by Tables A and C in proportion to the length of the ship covered by those erections.

Table B.

All vessels equal in strength to Lloyd's spar-decked rule, or which, although in excess of that rule, do not come up to Lloyd's requirements for ships of full scantlings to the upper deck, are to be considered as spar-decked ships, the freeboard for which will yary with their strength.

When the height between decks is greater or less than 7 feet, the consequent modification in freeboard will vary from $\frac{1}{3}$ to $\frac{2}{3}$ the excess or deficiency of height, the exact proportion to de-

pend upon the strength of the vessel.

In spar-decked vessels where the height between main and spar deck exceeds 7 feet, the numbers for scantlings should be found assuming the height between decks to be 7 feet; if both these numbers are in the same grades as the actual scantling numbers of the vessel, the correction for height between decks is to be \(\frac{1}{2}\) of the excess of height above 7 feet. If both the scantling numbers so found are in higher grades than those of the actual vessel, \(\frac{2}{3}\) of the excess of height is to be added, and if either one of these scantling numbers is in a higher grade, \(\frac{1}{2}\) of the excess of height is to be added. The same principle will apply in cases where the height between decks is less than 7 feet.

Since the freeboard is measured from the spar deck, it will be increased if the 'tween deck height is more, and decreased if it

is less than 7 feet.

In computing the freeboard of spar-decked vessels having scantlings in excess of Lloyd's requirements, a comparison is to be made between their scantlings, the scantlings of vessels of the same dimensions classed 100 A built to the three-decked rule, and of vessels built to the 100 A spar-decked rule, and the freeboard is to be proportionate between that given in Table A and that given in Table B, after deducting 12 per cent from the former; but in no case must the freeboard so assigned be less than that provided in Table A, for a vessel of the same dimensions, sheer, and camber, or round of beam, and deck erections.

In the comparison of scantlings and assignment of freeboard to spar-decked vessels having scantlings in excess of Lloyd's re-

quirements, the following method is to be adopted:

1. The difference between the freeboard by Table A (less 12 per cent) and that by Table B to be divided by five, \(\frac{3}{2}\) of it being considered with reference to the longitudinal strength, and \(\frac{3}{2}\) of it with reference to the transverse strength, these allowances to be the maximum deduction on each account.

2. In the comparison of steel ships, notwithstanding the general reduction of 20 per cent for steel as compared with iron thicknesses, outside plating in the way of the double bottoms is not to be further reduced by $\frac{1}{20}$ unless its thickness is $\frac{1}{20}$ or over. No reduction is to be made in any case unless there are floors connected with every frame.

3. In the calculation of strength the following method is to

be adopted:

- (a) Thin iron or steel plating in weather decks and the inner plating of double bottoms are to have their sectional area reduced for the purpose of the strength calculation as follows:
- 1. When the deck beams or floors are fitted on every frame of the usual spacing:

Thickness	in	20ths.							5	6	7	8	9	9
									6	. 7	. 9	1		1

2. When the deck beams or floors are fitted on alternate frames:

When the decks are sheathed with wood, with fastenings not more than 24 inches apart, the factors given in (1) are to be used, whether the beams are on every frame or on alternate frames, but if the fastenings are 48 inches apart, then the factors in (2) are to be used unless the beams are fitted on every frame.

(b) A deduction of $\frac{1}{2}$ is to be made for rivet holes in steel, and

in iron for the parts in tension.

(c) Iron or steel decks which cover not less than $\frac{2}{3}$ of the midship length of the vessel are to be considered in the calculation just as they would be if of the full length.

(d) Such portions of wood weather decks as are continuous throughout the midship portion of the ship are to be considered

as equivalent to steel of $\frac{1}{25}$ the section area of the wood.

(e) For the purpose of comparison of strength the breadth of the hatchways in the standard vessel shall be deemed to be \(\frac{1}{2}\) the breadth of the deck, and the tie-plates should be assumed to be fitted at the side of the hatchways.

Table C.

The standard of strength for awning-decked vessels is that provided by Lloyd's Rules (1885) for 100 A awning-deck class, as modified and extended by the following table showing the thicknesses of topside plating, etc.

All vessels equal in strength to the above standard, or which, although in excess of that standard, do not come up to Lloyd's requirements for a spar-decked vessel, are to be considered as awning-decked vessels, the freeboard of which will vary with their strength.

No modification is necessary in respect of the height of 'tween

decks of awning-decked vessels.

In comparing the freeboard for awning-decked vessels having scantlings in excess of the standard requirements, a comparison is to be made between their scantlings, the scantlings of vessels of the same dimensions built to the 100 A spar-decked rule, and of vessels built to the standard awning-decked rule, and the freeboard is to be proportionate between that given in Table B and that given in Table C.

In vessels where the superstructure is of less strength than that required for the standard awning-decked vessel, additions

are to be made to the freeboard in the same proportion.

In the comparison of scantlings and assignment of freeboard to awning-deck vessels having scantlings in excess of the standard awning-decked vessel, the method of procedure to be similar to that stated above for spar-deck vessels having scantlings in excess of those provided by the spar-decked rule.

The thickness of the side plating above the main deck of standard awning-decked vessels, for half the vessel's length

amidships, is to be in accordance with the following table.

Ratio $rac{L}{D}$.	Under 13.	13–14	14–15
Plating Number 10,000 and under 13,100 13,100 " " 15,500 15,500 " " 16,600 16,600 " " 18,700 18,700 " " 26,400 26,400 " " 30,900 30,900 " " 35,200 35,200 " " 40,000	5 6 6 7 8 8 9* 9*	5 and 6 6 and 7 7 and 8 8 and 9* 9* 10*	6 6 7 8 9* 9 and 10* 10†

* The butts of the awning-deck sheer strake to be treble riveted, and the landing edges of the side plating to be double riveted.

† The butts of the strake of side plate below the awning-deck sheer strake to be

The butts of the strake of side plate below the awning-deck sheer strake to be treble riveted in addition.

Note.—For iron read sixteenths and for steel read twentieths of an inch. When two thicknesses are given the greater is that of the awning-deck sheer strake. The depth and length are to be measured as defined in Lloyd's Register Rules for estimating the scantling numbers.

When Section 46 of the above rules (relating to vessel's proportions) applies to these vessels, the increased thicknesses required for sheer strakes, stringers, etc., are to be added to those of the main deck.

When one steel deck is required, it is to be fitted at the main deck, and when two steel decks are required they are to be fitted at the awning-deck and the main-deck, for the purpose of comparison of strength for determination of freeboard.

For vessels having a plating number exceeding 40,000 the scantlings necessary for the standard awning-decked vessel for the Table C freeboard are to be determined so that the stress per square inch upon the material of the hull amidships shall not exceed that of a standard vessel of the same dimensions and form, and having scantlings equal to the requirements of the 100 A class in Lloyd's Register for three-deck vessels when loaded to the freeboard given in Tables A after deducting 12 per cent from the same.

In part awning-decked vessels with raised quarter-decks and long superstructures with the extra strength given in Section 44, Lloyd's Rules for 1889 for iron and steel vessels, where the break of the quarter-deck is $\frac{1}{10}$ the vessel's length abaft amidships, and the continuity of strength is suitably maintained at such break, a reduction may be made from the freeboard required by Table C in accordance with the following scale.

101

When the break of the quarter-deck is not less than r_0^8 the length of the vessel abaft amidships, twice the above mentioned allowance may be made, and for intermediate lengths of erection the allowance is to be obtained by interpolation.

Vessels with plating number under 18,000, 2½ inches. Vessels with plating number 18,000 to 21,000, 3 inches. Vessels with plating number 21,000 to 24,000, 3½ inches. Vessels with plating number 24,000 to 27,000, 3½ inches.

In part awning-deck vessels the standard height of the raised quarter-deck is 4 feet; for raised quarter-decks of less height, extending over 40 of the length, the allowance for the erections should be diminished as shown in the following table:

HEIGHT OF R.	MOULDED DEPTH OF VESSEL IN FEET.													
QUAR. DE.	Ft. In. 10 0	Ft. In. 12 0	Ft. In. 14 0	Ft. In. 16 0	Ft. In. 18 0	Ft. In. 20 0	Ft. In. 22 0							
Ft. Ins. 3 6 3 0 2 6 2 0 1 6	Ins 1 1 1 1 2 2	Ins. 1	Ins. 1/2 1 1/2 2/1 3	Ins. 1/2 1 1/3 2/3 3/3 3/4	Ins. 1/2 1/4 2 31/4 41/4	Ins. 11/2 21/2 33/4 5	Ins. 3 13 3 41 6							

For shorter or longer lengths of raised quarter-decks a proportionate correction should be made.

Table D.

Sailing vessels classed A (black) in Lloyd's Register are to be

regarded as first-class ships in applying the tables.

Hard wood ships, i.e., other than fir or pine, classed A (red) in Lloyd's are to have their freeboards by the tables increased by 8 per cent.

Hard wood ships classed Œ in Lloyd's are to have their free-

boards by the tables increased 15 per cent.

Hard wood ships without class are to have their freeboard by the tables increased by 20 per cent, unless opened out for survey, when their freeboards will depend upon their condition.

Soft wood ships will require to have their coefficient of fineness modified in respect of the excess of the registered breadth caused by the extra thickness of side. That for hard wood ships is already provided for in the tables.

Soft wood ships classed A (red) in Lloyd's are to have their freeboards by the tables increased 10 per cent.

Soft wood ships classed Œ in Lloyd's are to have their free-

boards increased 20 per cent.

Soft wood ships without class are to have their freeboards by the tables increased 25 per cent unless opened out for survey

when their freeboards will depend upon their condition.

Iron and steel sailing vessels having a greater rate of rise of floor than 1½ inches per foot of half breadth may have the moulded depth to be used with the tables reduced by half the difference between the total rise of floor at the half breadth and the total rise at the standard rate of 1½ inches per foot; 2½ inches per foot of half breadth is to be the maximum rate of rise on which an allowance is to be made. When the reserve buoyancy is calculated, the percentage taken shall be that corresponding to the depth reduced as above, but in no case shall the free-board be less than that given in the top line of Table D for such percentage. Whichever method be adopted the correction for length is to be applied in relation to the reduced moulded depth.

RULES TO REGULATE THE DEPTH OF LOADING OF TURRET-DECK VESSELS AND VESSELS OF SIMILAR TYPES.

1. A turret is a strongly-constructed continuous erection at the middle line of the vessel, forming with the main or harbour deck an integral part of the hull, having a breadth not less than f_0^* of the greatest breadth of the vessel and a height not less than 25 per cent of the moulded depth. In assigning free-boards to turret-deck vessels, the following rules should be observed:

2. Hatch coamings at least 2 ft. high and casings to engine and boiler openings at least 4 ft. 6 ins. high to be fitted above

the "turret" deck.

Any scuttles or other openings in the harbour deck are to be closed water-tight by means of iron or steel plates not less in thickness than the harbour deck, suitably stiffened and strongly bolted in place. The following method of computing the free-board is based on the consideration that the turret-deck hatchways are provided with permanent means of closing them, as described in clause 8 of the rules for shelter-decked steamers.

3. The volume of the turret to be estimated from a normal beam line drawn through the point where a vertical line at the quarter breadth of vessel cuts the upper surface of the vessel's deck. Where the turret is nearly one-half the breadth of the vessel, and its transverse section is of rounded form at its base, the base line of the turret is to be drawn through the point where the vertical line at the quarter breadth cuts the upper surface continued in the same curve as the normal line of beam.

4. The reserve buoyancy required by the tables to be estimated by taking 70 per cent of the volume of the turret. The height of the turret allowed for is not to exceed 25 per cent of the moulded depth. (It is to be understood that no correction is to be made for an unsheathed iron harbour deck in applying the buoyancy method.)

5. The moulded depth of the vessel to be taken to be the depth at side from the beam line, as before defined, to the top

of the keel.

6. If a vessel has sheer, to determine the volume of the turret, the turret base line to be drawn at each section as described above. At the extreme fore end of the vessel the base of the turret to be parallel to the turret deck.

7. Where a poop and forecastle or a forecastle only are fitted on the top of a turret, the allowance for them is to be as follows:

When the effective length of these erections is equal to \(\frac{1}{8} \) of the vessel's length, deduct 8 per cent of the difference between the freeboards in Table A (after correction for sheer) and Table C.

For erections of greater or less length the allowance is to be in proportion to the length. The allowance for such erections is not to exceed 10 per cent of the difference between the free-boards in Table A (after correction for sheer) and Table C.

The effective length of a poop or forecastle is to be obtained by multiplying its actual length by the ratio which its breadth bears to the breadth of the ship at the after end of the forecastle or fore end of the poop respectively.

The provisions of the freeboard tables regarding the height of forecastles, the bulkheads at the after end of forecastles and at the fore end of poops, and the means of closing the openings

in poop bulkheads, are to be applied in these cases.

ŝ. The method described above is only applicable when it is possible to obtain a correct drawing of the "lines" of the vessel, and it is only to be employed when facilities are given for verifying the drawing by actual measurements at the ship, in accordance with para. 6 of the freeboard tables. When a verified drawing is obtainable, either the foregoing or the following method may be employed at the option of the owner, but if a verified drawing is not obtainable, the following method only is to be employed.

9. The depth of hold to be used in obtaining the coefficient of fineness in vessels having either an excess or deficiency of sheer is to be modified as described in para. 3, and the coeffi-

cient thus obtained is to be modified when the vessel is of rounded form at the gunwale, the necessary addition in ordinary cases

being .01.

10. The length correction under para. 9 of the load-line tables is to be $\frac{3}{4}$ of that specified in Table A, where the breadth of the turret is $\frac{5}{10}$ of the breadth of the vessel, but the table correction is to be halved where the breadth of the turret is $\frac{5}{10}$ or more of the breadth of the vessel. For turrets having breadths between $\frac{5}{10}$ and $\frac{6}{10}$, the length correction is to be in proportion.

11. In making the sheer correction in accordance with para.
18 of the load-line tables, the sheer is to be measured at the

ends of the vessel.

12. The effective length of the turret is to be obtained by multiplying its length by the ratio of the mean breadth of the turret to the breadth of the vessel amidships.

13. The deduction from the freeboard shown in the tables on

account of the turret is to be as follows:

Where the effective length of the turret is $\frac{5}{10}$ of the length of vessel deduct 45 per cent of the difference between the free-boards in Table A (after correction for sheer) and Table C. Where the effective length is $\frac{5}{10}$, deduct 55 per cent, and so on in proportion. For intermediate lengths intermediate percentages are to be taken.

14. In those vessels having unsheathed harbour or main decks, a correction should be made, when employing the linear

method of computation, as described in para. $\hat{6}$ (b).

15. The transverse and longitudinal strength of the vessel are to be regulated by that required for a "three-deck" vessel of the same length, breadth, moulded depth, and coefficient of fineness, and the scantlings of the turret are to be determined so that the stress per square inch upon the material of the turret amidships shall not exceed that of a standard vessel of the same dimensions and form, and having scantlings equal to the requirements of the 100 A class in Lloyd's Register (1885) for three-deck vessels when loaded to the freeboard given in Table A after deducting 12 per cent from the same.

16. Should a vessel be constructed with a turret less than ½ the breadth of the vessel or less in height than ½ of the moulded depth, or should the radius of curvature at the gunwale exceed 20 per cent of the moulded depth, or should the centre line of the disc when ascertained reach a point above the junction of the vertical side with a rounded gunwale, full particulars and calculations with the proposed assignment are to be submitted

to the Board of Trade before freeboards are assigned.

17. The freeboards in the certificates issued are to be set off in feet and inches from the line of the turret deck.

RULES FOR THE DETERMINATION OF THE FREEBOARD OF SHELTER-DECKED STEAMERS

By the term "shelter-decked steamer" is meant, for the purpose of the following instructions, a steam vessel having a complete superstructure of a substantial character extending over the whole length of the vessel, the superstructure deck (hereinafter called the shelter-deck) being continuous and unbroken at the sides of the vessel, but having one or more openings at the middle line, which have no permanent means of closing them, but which may not have means for temporarily closing them.

All hatchways in the deck immediately below the shelter-deck should be properly framed with substantial coamings, hatch covers, and shifting beams, etc., as described in paragraph 24. The hatchways should have efficient means of battening down as described in clause 7 of these rules and any stairways or similar openings should have efficient means of

closing.

In assigning freeboards to shelter-decked vessels, the follow-

ing rules should be observed:

(1) In making the sheer correction in accordance with para. 18 of the load-line tables, the sheer is to be measured at the ends of the vessel, and the freeboard corrected for sheer in esti-

mating the allowance for erections.

(2). (a) In the case of shelter-decked vessels having only one opening in the shelter-deck, the length correction under para. 9 of the load-line tables is to be one-half that specified in Table A; and the allowance for deck erections is to be determined under para. 11 in the manner specified below, provided that the effective length of the deck erections, when assessed on the assumption that the opening in the deck is an open well, and in accordance with the different regulations contained in the load-line tables affecting poops, bridges, and forecastle, open or closed, is not less than $\frac{1}{10}$ of the length of the vessel.

(b) In the case of shelter-decked vessels having an opening at each end of the vessel, and also in the case of vessels having more than two openings in the shelter-deck, the allowance for deck erections is to be determined under para. 12 of the tables, the length correction under para. 9 of the load-line tables is to be one-half that specified in Table A, provided that the effective length of the deck erections, when assessed on the assumption that each opening in the deck is an open well, and in accordance with the different regulations contained in the load-line tables

affecting poops, bridges, and forecastles, open or closed, is not

less than $\frac{6}{10}$ of the length of the vessel.

(3) The effective length of the deck erections is to be calculated in the following manner, provided the openings in the shelter-deck do not exceed half the vessel's breadth at the middle of the length of the opening. The length to be taken in the first instance as if each opening were an open well, the value of each part being assessed on that assumption in accordance with the different regulations contained in the load-line tables affecting poops, bridge-houses, and forecastles, open or closed, and also in accordance with the regulations regarding bridge-houses not covering the engine and boiler space. The final allowance for erections will depend upon whether or not temporary but efficient means are provided for closing the openings in the shelter-deck.

(a) If efficient means as specified below are provided for temporarily closing the openings in the shelter-deck, the effective length of the deck erections is to be reckoned as the length computed as prescribed above, plus half the difference between

that length and the length of the vessel.

(b) If efficient means for temporarily closing the openings are not provided, the effective length of the erections is to be computed by adding to the length computed as above one-fourth, instead of one-half, the difference between that length and the length of the vessel.

(c) If the openings in the shelter-deck are wider than as specified above, the addition to the assumed length of erections is to be modified in proportion to the relation which the actual opening holds to the specified breadth and to a complete well.

4. Means for temporarily closing the openings in the shelter-deck may be regarded as efficient, if they are at least equivalent to the following in strength and security. The portable planks for closing the openings to be not less in thickness than required by para. 43 of Lloyd's Rules (1885) for the flat of awning-decks. The planks to be supported by portable beams, fitted either longitudinally or athwartships, spaced not wider than 5 feet apart, and efficiently secured at their ends, and the deck in way of the openings to be efficiently supported by pillars from the deck below. The portable planks to be provided with eye bolts and lashings, or some other equally efficient means of securing them in place.

5. If efficient means are provided for temporarily closing the openings in the shelter-deck in heavy weather, the freeing ports required by para. 11 (e) need not be provided. If, however, efficient means for closing the openings are not provided, whether in vessels with one or more than one opening in the shelter-

k, then freeing ports with shutters properly hung are to be ed, having a minimum area as follows:

LENGTH OF OPENING	FREEING PORT AREA ON
IN THE SHELTER-DECK,	EACH SIDE IN SQUARE
FRET.	FEET.
5	4.5
10	6.5
15	7.5
20	8.5
25	9.0

f the freeing port area is less than that stated above, an lition is to be made to the freeboard of ½ per cent of the vessel's ulded depth, provided, however, that in the case of vessels ated under para. 12, the freeboard is not to be increased bend that due to deck erections of the same length and character, with open wells, as determined by the different regulations tained in the load-line tables affecting poops, bridge-houses, i forecastles.

5. The deduction for summer to be intermediate between bles A and C, in proportion to the effective length of erections ally allowed for freeboard purposes, and the freeboards igned to those vessels must never be less than would be igned for a complete awning-decked vessel of the same dimenns.

7. For the purpose of the assignment of freeboards, a hatchy having strong iron or steel coamings, with hatch rest bars the usual description, and also cleats for battening down bars urely riveted to the coamings, thwartship beams and fore 1 afters, substantial hatch covers and tarpaulins, shall be conered to have "permanent means of closing." And a deck ction having no openings in it, except so protected, shall be d to be "permanently enclosed."

he above reduction in freeboard for summer voyages from European and literranean ports is to be made from April to September inclusive. In other ts of the world the reduced freeboard shall be used during the corresponding recognised summer months. Double the above reduction to be allowed for ages in the fine season in the Indian seas, between the limits of Suez and gapore. An additional freeboard of two inches should be required for all sels up to and including 330 feet in length when entering the North Atlantic, an sailing to, or from, the Mediterranean, or any British or European port, which may sail to, or from, or call at, ports in British North America, or ern ports in the United States, north of Cape Hatteras, from October to whinclusive.

Load Draught Diagrams.

(Based on British Freeboard Tables.)

It is often necessary to get an approximation to the load draught in estimating on proposed vessels, when in many cases there is insufficient time to calculate the freeboard in the regular way. For this purpose the adjoining diagrams have been prepared for cargo vessels from the freeboard tables, and from these the mean moulded load draught may be scaled off with accuracy, always observing that the proper allowances for excess of sheer, erections on deck, and uncovered iron deck, strength, etc., must be made afterwards. These diagrams being graphic reproductions of the various tables, will be found to facilitate the estimating of load draughts where a sufficiently close approximation only is required. It should also be borne in mind that fullness of form influences the freeboard to a considerable extent, therefore the diagram will only read correctly for vessels having coefficients of under deck tonnage from .78 to .82, and judgment must be used when dealing with vessels of finer forms, the freeboards of which are less than in the case of fuller vessels.

CHAPTER V.

KIRK'S ANALYSIS.

(Trans. Inst. of Nav. Arch.)

The following was the method adopted, and here I may premise that for ordinary purposes I assumed that the length of entrance and run were equal—in fact I contented myself by finding the mean of the lengths and angles of entrance and run—but the method is equally applicable to finding them separately when greater accuracy is required.

I shall now give the process for finding the mean length and

angle of entrance and run.

Construct a block ship having the same displacement, mean draught, and area of midship section as the ship under consideration, but with rectangular sections, parallel middle body (if necessary) and straight-sided wedge-shaped ends. Fig. 34 shows by the curved line IBK the midship section of the actual ship, and by the rectangle CLME the midship section of the block ship, both sections being equal in area and depth, having a common water line IK. The depth AB is the mean draught of the ship. Fig. 35 represents the block ship, and ABDC is the half-breadth plan, the sides being vertical, the transverse sections all rectangular, and the keel parallel to the water line. The sides CD and EF which form the middle body, are parallel to the keel (or to the centre line AB), and the half-breadth GC or HD is equal to AC, Fig. 34, the half-breadth of the equivalent rectangular midship section (which is in fact the midship section of the block ship), EL being also equal to AB. The angles CAG and DBH are equal, and while the length AB is equal to the length of the ship, the length AG or HB of equal wedges which form the ends is such that the area of the figure ACDBFE multiplied by the mean depth AB, is equal to the volume of the displacement of the actual ship.

Complete the rectangle COPE as in the dotted lines. It is obvious that the rectangular solid COPELQ is equal in volume to that of the block ship, in fact to the volume of the displacement of the actual ship, and that the length

$$GB \text{ in feet} = \frac{\text{Displacement in cubic feet}}{\text{Area of midship section in square feet}},$$

and the mean length of entrance and run

$$AG = \text{length of ship} - \frac{\text{Displacement}}{\text{Midship area}}$$

Area midship section also. The breadth CE =Mean draught (ex. keel)

and the tangent of the mean halfangle of entrance and run,

$$CAG = \frac{GC}{GA}$$
.

Thus from the length, breadth, draught, area of midship section, and displacement, the mean length of entrance and run and the mean angle can be got. There are other methods of working this out, which will occur to any one, but the method given is perhaps

the simplest.

In order to get the length and angle of entrance and run separately (instead of the mean as stated), it is necessary to have in addition, the displacement in two portions, one forward of the midship section, and one aft, the distance of the midship section from one end of the ship, and the mean draught of each of these portions; treating them, in fact, as two separate ships, one of which has no run and one no entrance.

In my earlier attempts I retained the actual breadth of the ship as the breadth of the block ship, and varied the depth, but I prefer the plan before given of using for the block ship the mean draught of the actual ship. ships with extremely raking sterns or stern posts, I take the length at half depth when that can be got (or the mean length) as the length of the block ship. In single screw steamers, I take the length to the forward stern post.

The block ship will often be found of use in forming first or

approximate designs, and in this view it may be interesting to compare the wetted skin surface of actual ships with that of the equivalent block ships, this being an important element in speed calculations and otherwise.

In the foregoing table I have selected fourteen ships of very diverse types, giving their dimensions, block models, actual wetted surface (exclusive of that of keels or rudder), and wetted

surface of block ship, and the ratio of one to the other.

From this it will be seen that in first approximations in comparing one ship with another we shall not commit a grievous error in using the surface of the block ship, and also that a very close approximation indeed may be made to the actual wetted surface by multiplying the surface of the block ship by one of the coefficients in the table, according to the type of the ship. In the second column SS means single screw, TS means twin screw, and P paddle. In No. 10 I ought to explain, that not only was the rudder of exceptional breadth, part of which, to make the comparison with the others more even, has been included, but there was a peculiar overhanging portion under water near the top of the stern post, by which the mean length taken for the block ship exceeds that of the actual ship between perpendiculars.

To show more clearly the relation of the block model to that of the actual ship, I have selected No. 4 in the table, as being a fair example of a merchant mail steamer of considerable speed, and in Fig. 36 I have given the curve of areas of transverse sections; and I have put it in this form that the ordinates are equal to the half areas of the corresponding transverse sections divided by the draught of water (less depth of keel) at the several sections. This is in fact the curve of form, or fineness of model.

Above this I have drawn the half-breadth plan of the block ship, the length, breadth, and area of this being of course equal to those of the curve, and the length and angle of entrance and run a mean of those of the actual curve of form.

Wetted Surface Formula.

$$\mathbf{W.S.} = L \times \left(\frac{B}{2} + dr\right) \times c.$$

Where W.S. = wetted surface of hull proper in square feet, excluding bossing, rudder, bar keel, etc.

L =length on load water line.

B = extreme breadth.

dr = extreme draught in flat plate keel vessels, and draught corrected to flat plate keel conditions in bar keel vessels.

c = constant from the following table:

RATIO OF	$\frac{B}{dr} = 5.00$	3.33	2.50	2.00	1.667
Block Co- efficient.	-		Values of "c	••	
.40 .45 .50 .55 .60 .65 .70 .75	1.120 1.167 1.215 1.272 1.330 1.397 1.465 1.542 1.620 1.708	1.130 1.184 1.238 1.299 1.360 1.427 1.494 1.565 1.637 1.715	1.153 1.211 1.270 1.330 1.390 1.456 1.522 1.588 1.655 1.724	1.180 1.240 1.300 1.360 1.420 1.480 1.541 1.604 1.668 1.733	1.200 1.260 1.320 1.380 1.440 1.500 1.560 1.680 1.740

Wetted Surface (Taylor's Formula).

W.S. =
$$c\sqrt{D\times L}$$
.

where W.S. = wetted surface in square feet, excluding rudder, bossing, etc.:

D =displacement in tons of 35 cubic feet.

L = mean immersed length.

B =breadth extreme.

H = draught of water, extreme in flat plate keel vessels, and corrected to flat plate keel conditions in bar keel vessels.

c =constant found from the following table:

RATIO $\frac{B}{H}$.	CONSTANT "c."	RATIO $\frac{B}{H}$.	CONSTANT "c."
2.0	15.63	2.8	15.55
2.1	15.58	2.9	15.58
2.2	15.54	3.0	15.62
2.3	15.51	3.1	15.66
2.4	15.50	3.2	15.71
2.5	15.50	3.3	15.77
2.6	15.50	3.4	15.83

Note. — This formula becomes unreliable when the block coefficient is beyond the limits of .45 and .75, or when the ratio of $\frac{B}{H}$ is outside the limits given in the table.

CHAPTER VI.

LAUNCHING.*

The form of ways for ordinary merchant ships is of comparatively little importance; but in special cases, such as armored war vessels or long, light river boats, if there is too little water on the way ends, the vessel is liable to tilt as soon as her C.G. gets over the way ends, and being as it were pivoted at this point, a great pressure is put upon the bottom of the vessel, causing undue local strains, which might possibly force in the bottom plating, frames, etc., in those vessels which are not so strongly constructed as ordinary merchant vessels, or the ways might collapse here and then

- 1. COMMENCEMENT OF 18T PERIOD
- 2. CHANGE BETWEEN 18T & 2ND PERIODS
- 3. END OF 2ND PERIOD

the vessel would be left to slide off the remaining distance on her keel. To guard against this danger, it is desirable to ascertain by calculations and diagrams if the form of the ways is such that the vessel may be launched without fear of tilting.

The time that a vessel takes to travel down the ways may be divided into two periods — the first lasts while she rests entirely

Paper by H. G. Gannaway, Trans. E. Coast, Eng., and Shipb'd, 1887.

on the ways, and the second, when the stern is afloat and the fore end of the ship is bearing on the fore end of the sliding ways.

A base line is first drawn, the measurements along which represent distances travelled by the ship down the ways, the total length in this case being 267 feet. The line AA drawn parallel to the base represents the moment of the ship about the fore end of the sliding ways. In this example the ship's weight is 865 tons, which being multiplied by 97.2 feet, the distance of the C.G. of the ship from the fore end of the sliding ways. = 84.121 foot-tons. The buoyancy moments about the same point are represented by curve B. The position of intersection of this curve with the line AA will indicate where the vessel will be when her stern commences to float aft. At this point the first period ends and the second commences, which in the example is when the vessel has travelled 208'6" down the ways. Although this is the point where the moments of buoyancy and weight about the fore end of sliding ways become equal, the vessel's stern does not actually lift until she has moved a few feet beyond this, because an additional amount of displacement is required to overcome the vertical component of the ship's momentum.

Observations of the dip of the vessel's keel have proved that this additional displacement is so trifling that a complete investi-

gation of its amount is unnecessary for ordinary purposes.

The displacement of the vessel throughout the first period is shown by curve D^1 , and for the second period by curve \bar{D}^2 . During the second period, the after end of the vessel being affoat, and the fore end resting on the sliding ways, it is evident that the buoyancy moment about that point will remain the same as the weight moment all throughout this period. The displacement, of course, increases as the vessel moves down the ways, but the gradual lifting of the stern and lowering of the bows brings the C.B. further forward, and so reduces the leverage while the displacement is increasing, thus retaining practically a constant moment. The distance that the line CC is above the base, represents the weight of the ship, the weight on the fore end of the sliding ways being proportional to the distance between this line and curve of displacement D2. This weight is 225 tons at the beginning of the period, and is reduced to 115 tons at the end. It is important, therefore, that the fore end of the cradle should be made sufficiently strong to carry the load which is thus put upon It will be seen then that it is desirable to reduce the duration of the second period as much as practicable, for, since the longer it is, the greater the weight will be on the fore end of the sliding ways, which in the case of heavy vessels renders them liable to come down to the ground and damage their fore ends.

In considering the subject of tipping, we take the moments

about the end of the standing ways, and as long as the buoyancy moment remains in excess of the weight moment about this point, there is no fear of the vessel tipping; but if in any position the former moment falls short of the latter, it is evident that in order to restore equilibrium, the stern will drop, and thus increase the displacement until both moments are equal. Tipping, if occurring at all, must take place after the C.G. of the ship has passed the end of the standing ways, and before the commencement of the second period. In the example, the C.G. of the ship has passed

the way ends when she has moved 174 feet. From about that point to a little beyond the end of the first period, the buoyancy and weight moments about the end of the standing ways are calculated at several intervals, and at each interval the latter moment, being deducted from the former, gives the moments against tipping. These moments are shown by curve E. If this curve at any part were to run below the base line, it would show that the vessel will tilt. The point where this curve is nearest to the base line gives the position of the vessel when she has least longitudinal stability, which in this case is when the vessel has travelled down the ways 189 feet, the minimum margin against tipping being 9,700 foot-tons.

It is desirable that the margin be not too small for uncertain vessels; where this was the case they actually did tilt slightly, which shows that a moderate margin is required in calculation to allow for the error introduced by treating, as it is convenient to do in practice, those moments statically instead of dynamically. In calculating the buoyancy moments no account is taken of the cradle, which would only alter the results slightly; the variations being on the right side, may be safely ignored. Besides, the attern

end of the sliding ways often rises to the surface shortly after the vessel has entered the water. In the diagram a complete set of curves has been given to fully illustrate the matter, but for practical purposes only that part of the diagram where the vessel is represented to be moving from the position where the C.G. is at the way ends, to the end of the second period, is required.

As the minimum moment against tipping is a very important thing, it will be useful to know what variation will be made in its amount by any alteration to the length and form of the standing ways of this vessel:

Lengthening the standing ways 10 feet increases the moment

from 9,700 to 13,700 foot-tons.

Shortening the ways 10 feet decreases the moment to 5,300 foot-tons.

Increasing the camber from 12 inches to 18 inches increases the moment to 14,500 foot-tons.

Decreasing the camber to 6 inches decreases the moment to 4,000

foot-tons.

If with a certain declivity of ways for the launching of a vessel, it is found, by calculation, she will tilt, the standing ways must be extended further out into the water, or, if this cannot be done conveniently, their outer ends must be lowered, or ballast put into the fore end of the vessel. The first two increase the buoyancy moment about the end of the standing ways, and the third decreases the weight moment about the same point.

Pressure on dog shores = $\frac{W \sin \delta - fW \cos \delta}{\cos \beta}$

W = weight of vessel.

 δ = mean angle of declivity of ways under vessel.

 β = angle between ways and dog shores.

f = coefficient of friction (between 1.0 and .7).

The ratio of second period to length of sliding ways cannot be got lower than about 25 per cent without danger of tipping.

RUDDERS.

In determining the most suitable area of rudder it is usual to take the same as a percentage of the immersed longitudinal plane of the ship, which percentage will vary with the degree of fineness of the vessel.

Percentage for Rudder Area in Various Types.

TYPE OF V	PER CENT OF IMMERSED LONGI- TUDINAL PLANE.					
Fast ocean liners						1.25
Freighters	-	-	-	-	:	1.50
Yachts						1.10
Paddle steamers						2.0

Having fixed upon the area, the diameter of stock may be calculated by various formulæ, some of them, unfortunately, of a very approximate character, and on this account, where high speed will be attained, it is advisable to carefully calculate the required diameter irrespective of the result obtained by the classification societies' formulæ. For this purpose it is necessary to know, (1) the hard over angle of rudder, (2) centre of pressure on rudder blade, (3) maximum pressure exerted at hard over with ship at full speed. The angle of helm being usually 35°, the pressure on blade at this angle at full speed may be found from the formula, —P representing the pressure in lbs.

$$P = AV^2 \times \sin \alpha \times p$$
.

It should be stated that V = speed of vessel in knots per hour plus 20 per cent to allow for the slip; A = area of rudder in square feet, including emerged surface; and p = pressure in lbs. per sq. foot at 1 knot, = 3.19 lbs. per sq. foot.

Before, however, the twisting moment on the stock can be solved, the centre of pressure must be located. This centre being 1 the breadth from the leading edge with the helm amidships, does not arrive at the centre of gravity of rudder until 90° is reached, and as 35° is the usual angle, it will be sufficiently close to take .37 of the breadth of the rectangle equalling the rudder area:

Centre of pressure from centre of stock = $l = \frac{A}{dr}$.37.

The twisting moment T would then be

$$T = AV^2 \times \sin 35^\circ \times 3.19 \times l = \text{inch-pounds}$$

and equivalent diameter of stock "d" in inches with a fibre stress k of 5,000 lbs.

$$d = \sqrt[8]{5.1 \ \frac{T}{5000}}.$$

The subjoined table gives torsional moments with their equivalent diameters calculated as above, with * 5,000 lbs. per square inch, being a sufficiently high fibre stress to allow for a twisting stress, alternating between right and left, for wrought iron

In a rudder of rectangular form the centre of pressure from the leading edge is equal to

$$b(.195 + .305 \sin a) = bc$$

where b is the mean breadth of rudder, and c a coefficient, as under.

c.	Angle of Rudder, a.	c.
248	35°	.370
.300	40°	.391
.347	45°	.410
	248	248 35° .300 40°

Rudder Stocks per Lloyd's Rule.

The following is the formula prescribed by Lloyd's Register for estimating diameters of rudder stocks, but in no case must the result be less than the tabulated rule size, which see. It should not, however, be used unless the ship is intended for classification in that society's register, as for very high speed vessels the results obtained would be too weak. One of the factors is draught of water, which has little or no value in computing the strength of rudder stock for a rudder of ordinary type hung on a post. Of course, in a rudder with no bottom bearing, as in destroyers and such craft, the case would be entirely different, as then the stock would be figured for bending, the moment for such being much in excess of the torsional one.

^{*} Take 7,000 lbs. for steel.

Rudder Stock Diameters.

Note. — Diameters are calculated to nearest eighths of an inch with a fibre stress of $5,000~\mathrm{lbs}$.

D = d raught in feet.

B =greatest distance in inches from

centre of pintle to back of rudder. b =greatest breadth of rudder in inches.

V =speed in knots.

d = diameter of stock in inches.

Then.

$$d = \frac{1}{32} \sqrt[3]{Db (2 B - b) V^2}$$
.

Rudder Stock per Germanischer Lloyd Formula.

This rule is a much more correct one than Lloyd's Register. using, as it does, truer factors. It is given here converted for English measure as well as for metric.

Let.

d = diameter of stock in centimeters.

F = area of rudder in square meters.

r =distance from centre of gravity of area to axis of stock in centimeters.

V = speed in knots.

Then,

$$d = .42 \sqrt[3]{FrV^2}$$
.

For English measure let

d = diameter of stock in inches.

A =area of rudder in square feet.

r =distance from c.g. to axis in inches.

V =speed in knots.

Then.

$$d = .103 \sqrt[3]{ArV^2}.$$

British Corporation Formula.

The "B.C.," or British Corporation, Rule is slightly different from the foregoing, but, like it, takes the true factors into account, and gives a more correct result than either of the foregoing formulæ.

$$d = .26 \sqrt[3]{rAV^2}.$$

NOTE. - "r" is here taken in feet.

PROPELLER STRUTS.

SIMPSON'S FORMULA.

Propeller "A" brackets or struts are not dealt with in any of the classification societies' rules, and in deciding on a suitable area of section for these, it is the invariable practice to base it on experience. Such being the case, a great divergence is found in the

proportions and dimensions of them in vessels of similar size and power. To insure greater uniformity in their design and weight consistent with ample strength to meet the stresses to which they are subjected, the writer has prepared the formula following, based on the results of a varied experience with struts for all sizes of vessels with a range of I.H.P. of 10 to 7,000 per shaft and revolutions of 70 to 600, and from observation of some which were actually carried away. It should be stated that the smaller powers were not for twin screws but for small craft with cut-away deadwoods necessitating a bracket to support the outer end of shaft. From the formula given, the area is obtained, and with it the following proportions determined:—

SECTION OF ARM

Let R = revolutions of engines per minute.

P = indicated horse power.

l = outboard length of shaft from stern tube outer bearing to centre of boss, in inches.

k = coefficient = .0633 R.

Then,

$$\frac{\sqrt[8]{R \times P \times l}}{k} = \text{area in square inches.}$$

Of course the horse power is that transmitted through one shaft only, and the area obtained is for one arm. The proportions of the pear-shaped arm are as under.

$$L = \sqrt{5.\dot{3} \times \text{Area.}}$$

 $B = .25 L$. $R = .25 B$.
 $l = .33 L$. $r = .50 R$.

For the lesser powers and for brackets intended for wood or composite vessels, the brackets should be of gun metal or bronze, and for higher powers and steel ships of cast steel.

Spectacle Frames.

For the larger classes of twin screw steamers what are known as spectacle frames are bolted to body post to take the outer end of shaft, and the shell plating webbed out to enclose what otherwise would be the outboard length of shafting, as described in chapter on design. These frames are of cast steel and semi-pear-shaped in section. The area of this section may be found from the same formula as if the ship were to be fitted with "A"

Fig. 39.

brackets and the result multiplied by 2. This greater area is accounted for by the fact that there is only one arm and the greater breadth of same required to permit of working the shell plating and also obtaining the necessary section modulus. The weight, however, will be found to approximate very closely to the open struts. Experiments have shown that better results are obtained by inclining the spectacle frame downwards at an angle of about 30° from the horizontal.

Proportions.

A=2L.	$F=\frac{3}{2}D$.
$B = \frac{1}{2} A$.	$L = \tilde{L}$ ength of pear-shaped
C = B.	section as got for "A"
$E=\frac{1}{2}D$.	bracket.

The outside diameter D of the boss will be fixed in conjunction with the engineer.

THE TRANSPORT OF CATTLE

In arranging the ship for the transport of cattle in conformity with the United States Department of Agriculture, care should be exercised in first providing for the main cattle gangways. A good location for these would be at the ends of engine or boiler casings opposite which the cattle doors should be placed. The webs. webframes, and any other structural obstructions should be arranged with a view to working them in as boundaries for blocks of 4 cattle if practicable, and if the ship be a new one, the frame spacing should be fixed to work out with the legal dimension for cattle pens to obviate waste of space, unsuitable pillaring, and division boards coming off beams. If the ship be of such dimension as to require 30" spacing ordinarily, then by increasing this to 301,", a very good arrangement of pens will be obtained. Coaling ports, mucking ports, and all thwartship passages in connection therewith, should next be located, bearing in mind, in arranging these, the 4-cattle blocks previously mentioned. The stalls may be then outlined, followed by the pillars, which, of course, will be placed to suit these, working downwards from the cattle deck to the other hold pillaring.

The following are the dimensions of cattle spaces required by

the Department of Agriculture:

Cattle per head on upper, spar, or weather decks:

8'0" long \times 2'6" wide \times 6'0" high in the clear.

Cattle loaded under decks will require 2 inches more width unless in regular cattle ships with satisfactory ventilation.

Pens must be arranged for 4 cattle, unless at the ends of a row

of pens, where 5 may be stowed.

Special permission must be obtained to carry cattle on lower deck, and in all cases where this is granted, the width allotted must be 2'8", the ventilation sufficient, and no animals are allowed on hatches.

Sheep, per head, $4'0'' \log \times 14''$ wide in the clear. Pens must not exceed 20 feet \times 8 feet where two tiers are carried, and each

tier to have a clear vertical space not less than 3 feet.

Horses, per head, 8 feet $\log \times 2'6''$ wide $\times 6'3''$ high in the clear, and as far as possible arranged between the overhead athwartship beams. Each horse must have a separate stall, and where 22 or more horses are carried, a hospital 8 feet \times 10 feet square must be reserved.

Alleyways for feeding and watering to be 3 feet wide, but where obstructions less than 3 feet long occur, and at ends of ship, they may be reduced to a minimum of 18 inches.

Thwartship alleyways to scuppers to be 18 inches wide.

Headboards not less than 2×10 inches or 3×8 inches, of spruce or yellow pine.

Footboards, same dimensions as headboards.

Division boards of 2×8 inches, spruce or yellow pine fitted vertically for cattle.

Division boards for horses, 2×9 inches $\times 8$ feet, planed and placed horizontally.

Footlocks, 2 inches above cement × 4 inches wide of spruce, yellow pine, or hardwood, ranged fore and aft, and placed 12 inches, 14 inches, 26 inches, and 14 inches apart; the first one being 12 inches distant from the inside of footboard; but when troughs are used, the footlocks will be placed 17", 16", 22" and 16" apart.

Outside planking on open and closed rail ships to be not less

than 2 inches spruce or 11 inches yellow pine.

Ventilators. Each under deck compartment not exceeding 50 feet in length, must have at least four 18-inch diameter cowl ventilators, with tops 7 feet above shelter deck, two being placed at each end of the compartment. If compartments be over 50 feet long, additional ventilators must be fitted.

Weight of Fittings per Head of Cattle Carried.

ITEM.		W	EIGHT IN LBS.

WEIGHT OF HULL

n estimating for displacement purposes, the weight of a ship's l is usually divided broadly into two parts, viz.: (1) finished 11 and (2) weight of wood and outfit.

here are various methods by which the steel may be estimated roxinately, but where great accuracy is required the weights the structure should be calculated in detail systematically, and results summarized in convenient form for future reference. The arrangement shown in the table will be found useful when cost estimate is being figured, as the parts of structure item-

l are those which generally show variations in labor prices. summary of material is given for a similar reason, and also the variation in scrap between the different items.

of course the structural parts considered in the table must each lealt with in detail, but by having some such form as that a presented the chances of omission will be minimized, the ghts put in a convenient form for prime cost, and also usefully unged if the centre of gravity should afterwards require calcung.

he most common method to approximate the weights of hull when there is insufficient time to figure in detail, is to take ratio between the weight and the cubic number of a known

Calculated Finished Steel Weight.

REFERENCE NUMBER.	PART OF STRUCTURE.	8.S. 430×46′×34¼′ LLOYD's 3-DECK RULE.	Summary.
1	Keel bars and stem.	Tons. 3.5	Tons. Forgings . 6.0

22	Finished steel weight . =	2990.0	

vessel of similar type and degree of fineness and use the coefficient so obtained on the proposed ship. For example, a known ship of length 330 feet, breadth 41' 9", and depth moulded 28' 3", has a total steel weight of 1,680 tons, then

$$\frac{L \times B \times D}{S \times 100} = \frac{330 \times 41.75 \times 28.25}{1680 \times 100} = .431 \text{ coefficient.}$$

The proposed steamer is $320 \times 42 \times 29\frac{1}{2}$ and the coefficient of steel weight being .431, we get

$$\frac{320 \times 42 \times 29\frac{1}{2}}{100} \times .431 = 1709$$
 tons.

This rough method requires good judgment and practice, as it is obvious from the example given that although 1,709 tons is a fair

approximation it is still too heavy.

Recognizing this fact and the necessity for a quick approximative rule which would give fairly close results, Mr. J. Johnson (vide Trans. Inst. Nav. Arch. Vol. 39) devised a method based on Lloyd's longitudinal number (modified for some types) and by plotting down known steel weights opposite their numeral, drawing curves through the mean values of each type, he analyzed them and found their equations. By means of curves prepared in this way from actual weights, the amount of steel is easily read off and the increase or decrease due to an alteration in the numeral is readily seen. Johnson's formula is as under,

$$W = cN^{\chi}$$
 or $W = K\left(\frac{N}{100}\right)^{\chi}$;

where

W = Finished weight in tons of iron or steel used in hull construction.

N = Lloyd's longitudinal number modified as follows: In 3 decked vessels the girths and depths are measured to the upper deck without deduction. In spar and awning decked vessels the girths and depths are measured to the spar or awning decks respectively.

In one, two or well decked vessels the girths and depths are taken to the main deck in the usual way.

c and K are coefficients varying with different types.

x is an exponent, also varying with different types.

Table Giving the Mean Values for c, K, and χ for Vessels Built to Lloyd's or Veritas' Highest Class.

Type of Vessel.	c.	K.	χ.
Three deck, with complete shelter deck Three deck Spar deck Awning deck One deck, two deck, and well deck Sailing vessels	.00359	.328	1.48
	.00078	.492	1.40
	.00115	.576	1.35
	.00167	.665	1.30
	.00215	.856	1.30
	.00065	.410	1.40

Of course differences in the arrangement of scantlings, extent of double bottom, number of bulkheads or length of erections must be calculated as extra.

A complete set of curves based on this method, but extended to embrace the largest types of vessels including complete shelter

deck steamers is given opposite.

The second part of the finished hull weight, viz.: the wood and outfit, embraces everything that goes to finish the ship excepting fresh water, coal and consumable stores. That is, it comprises all wood work, both shipwright and joiner, masts, rigging, sails, boats, anchors, chains, cables, hawsers, furniture, fixtures, etc., many of the items being extremely difficult of accurate calculation. For this reason it is necessary where these fittings are calculated in detail to carefully check the result obtained by a similar method to that used for the approximated steel weight from actual wood outfit data derived from known ships of similar type. The value of this coefficient for various classes will be seen from the Table of Elements of Ships.

Regarding this weight, Johnson states that it will be found to

vary almost directly as the longitudinal number.

Lloyd's Bulb Sections.

The depth in inches D of the section to be the base from which to deduce the other dimensions.

The width of the bubs to be $2\frac{1}{2}C$ for bulb angles, and $3\frac{1}{4}C$ for bulb plates and tees, when C is $\frac{D+3}{20}$ in the case of bulb angles, and $\frac{D+1}{20}$ for bulb plates and tees. The form of the bulbs to be

in accordance with the sketches.

The standard thickness for regulating the widths of bulb of beams and bars whose depth is not an exact number of inches, should correspond to the depth in inches next below the actual depth, thus—for tee beams and bulb plates $10\frac{1}{2}$ inches depth, the standard thickness to be used in determining the dimensions of the bulb should be $\frac{10+1}{20}$ or $\frac{11}{20}$. See figures 44 and 45.

Fig. 44.

C.G. BY EXPERIMENT.

All finished vessels should be inclined before leaving the builder's hands and their exact centre of gravity found experimentally. The value of this information cannot be over-estimated, although in many cases where possessed it does not seem to be applied with the care its importance demands, as evidenced by the proportions of many ships of the merchant marine.

Fig. 45.

The principle on which the experiment is based will be understood from a reference to Fig. 46, where p is a small weight placed on deck at centre line, and afterwards shifted to either side through a distance a. The centre of gravity before the movement was made is shown at G. It will be evident that this centre after the weight has been shifted, will move to a new location parallel to the line of shift, and that the weight multiplied by the distance through which it has been moved, will give a moment equal to the weight of the whole ship by the distance the common centre of gravity G has been moved to G_1 , so that we get:—

$$GG_1 = \frac{p \times a}{D}$$
.

Before attempting to carry out the inclining experiment, the

following preparations should be made, observing that although not imperative that the vessel be completely finished, it is well to have her in that condition if possible. The bilges should be

carefully examined to see that they are perfectly free from loose water, and the boilers, condenser, fresh water and ballast tanks must be either empty or pumped up "chock full," as any free water in the ship will destroy the value of the experiment. All workmen, unless those assisting, must be sent ashore, and when the shift is being measured the assistants and laborers

should be lined up on centre line of ship, a position they shall have occupied before beginning. The weather should be perfectly calm, and an enclosed space of water as a basin, or dock, selected, and the mooring lines eased off slack to permit the vessel to move freely.

The inclining weights should aggregate .5 to one per cent of the displacement, and two parallel lines should be marked off on deck amidships, representing the distance through which the centres of gravity of the weights shall be moved. A suitable position must be obtained, say in the engine or boiler hatch, in which to fix a large tee square with the cross head placed downwards, and a plumb line and bob attached at the end of the blade, care being taken that the bob swings clear of the square. When these preparations have been made and the inclining weights placed on deck, an accurate draught should be taken and the men ranged up on centre line, when a plumb line may be marked off on the edge of square as a starting point, the weights being thereafter transferred from the centre line to port or starboard and an observation made. The weights should then be moved right over to the opposite side. and the inclination noted. As a final check on the total shift the weights may be shifted back to their original position, when of course the plumb line should cover the point originally marked on starting. From the following data procured we shall be enabled to calculate the centre of gravity on the principle previously referred to, viz.: —

- (1) Draught of water.
- (2) Displacement from the foregoing.

(3) Weights shifted.

(4) Distance between the two lines representing the space through which weights were shifted.

(5) Length of plumb line from point of suspension to edge of square.

(6) Travel of plumb line from port to starboard, and starboard to port. Take mean.

(7) Condition of the ship as regards state of completion and what weights as cargo, coal, fresh water, water in boilers, ballast tanks and dunnage are on board.

As the vessel has been previously slacked off, on shifting the weights, it will be apparent that the ship will heel over so that the centre of gravity G, and the centre of buoyancy B_1 (Fig. 47), will be in the same vertical line and M will be the metacentre. Let α represent the angle of heel, then:—

Fig. 47.

The tangent of α is found by taking the length of plumb line "AB" and the mean shift of bob "BE" on tee square, from which we get:—

$$\tan \alpha = \frac{BE}{AB}.$$

The triangle GMG and BAE are similar, then

$$\frac{GG_1}{GM} = \frac{BE}{AB},$$

$$GG_1 = \frac{GM \times BE}{AB} = \frac{P \times a}{D},$$

$$GM = \frac{p \times a}{D} \times \frac{AB}{BE} = \frac{p \times a}{D \times \tan a}.$$

and

The height of M may be calculated for the draught with which we are dealing or directly measured from the metacentric diagram, and the GM as obtained above deducted from this height will give the centre of gravity above base at the time of the experiment. This height of course will require correction by deducting the inclining weights and the excess water in boilers, if these have been pumped chock full for the experiment.

Centre of Gravity.

The vertical centre of gravity of a ship is probably the most important point which the naval architect has to determine, as well as the most difficult to calculate with accuracy. Therefore it is that the calculation of this centre in detail is only resorted to when insufficient data derived from a somewhat similar type is wanting, as the most reliable method is that computed from actual centres obtained from experiments. However, where this is not obtainable, the calculation in detail by careful working out and good judgment should give equally accurate results. Where the former method is resorted to, the table of coefficients given in the chapter on Design will be found of service, observing that these are for the finished vessel loaded with a homogeneous cargo.

When, however, it is imperative to go into the calculation in detail, the simplest method will be to treat the hull proper as a

shell of uniform thickness, and when the centre of gravity as such is ascertained, to make the necessary additions for excesses on particular of strakes, keelsons, beams, deck plating, superstructure and wood, outfit and equipment weights. The centre of gravity of the machinery with steam to will be furnished by the engineers.

On a body plan of ten sections with half-end ordinates, mark off around the half girths of each section a spot every two feet apart, as shown on Fig. 48, dropping a perpendicular line from these locations to the base. Measure these heights above the base and tabulate them for each section, calling the centre line "O" as in the table. One side only need be dealt

with, as the ship is symmetrical about the middle line.

Each of the ten sections having been treated in a like manner to the foregoing, and the individual centres of gravity of all deter-

mined, these centres are then tabulated and the common centre a gravity found by a similar operation to the above, i.e., they are in tegrated by Simpson's multipliers, and the sum of the functions sobtained divided by the sum of the multipliers, when the resulting quotient will be the perpendicular height of the common centre a gravity of all the sections or of a shell of uniform thickness.

Another method to obtain the vertical height of C.G. due to form for a shell of uniform thickness is to take the sum of the functions of water line half-breadths of all sections from base to

gunwale, and divide them by the sum of the multipliers used, which will give a mean half-breadth for each water plane. By plotting off these mean dimensions, a mean section of the ship may be drawn on stout paper, cut out with a penknife, then pinned to port and starboard alternately and swung on a board having a plumb line scribed on as shown in Fig. 49.

The intersection of the mark points A and B with the plumb line, should be joined with the pin holes C and D, and where they cross each other on centre line will

Fig. 49.

be the mean height of centre of gravity. Carefully done, this will give a very close approximation to the calculation. Of course the usual additions as mentioned in the preceding method will be required to calculate the actual C.G. of vessel.

Outfit in detail, stores, fresh water, coal, etc., will be set down, giving the weight and estimated height of their respective centres of gravity from base, when the sum of the moments produced divided by the total weight will give a resulting quotient equal to the mean height of C.G. of ship from base without cargo, the centre of gravity of which may be found by a similar experiment, as it is customary to treat this as being of a homogeneous character.

CHAPTER VII.

STRENGTH OF SHIPS.

Ir is not generally considered necessary to make strength calculations for an ordinary merchant vessel when the scantlings are in accordance with any of the classification societies' rules, but in the case of a special design, and also in warships, it is advisable to do so.

In these calculations, the ship is considered as a girder and the principle is the same as that of a beam supported at both ends, or only at the middle, as may be the case for "sagging" or "hogging" respectively, uniformly loaded but unevenly distributed. As it is practically impossible to determine accurately the amount of stress that a ship will be subjected to when laboring in a seaway, it would seem quite legitimate to arrive at the necessary conclusions on the basis of comparison with other ships, which have proved to be sufficiently strong, and this is what is usually done in practice. In order that this information may be of use for comparative purposes, it is advisable to lay off the curves of weight, buoyancy, bending moments, etc., to some standard length and the mean weight or buoyancy ordinate to some standard height, so as to make the diagram as convenient as possible.

Curve of Weights.

The mean weight per foot of length of the total hull is calculated at convenient distances apart and these set up as ordinates from the base line of the diagram, at their corresponding stations, taking care to use the proper scale as previously determined on; the other heavy weights, as guns, armor, machinery, coal, homogeneous cargo, etc., are calculated separately and added as rectangles above the curve of hull weights. A mean curve is then run through these points, taking care that its centre of gravity comes over the centre of buoyancy and that the area circumscribed by the curve equals the displacement of the ship.

Curve of Buoyancy.

The displacement in tons per foot of length is then calculated at suitable intervals apart and set up as ordinates in the same manner as for the weight curve. The area enclosed by a curve passing through these spots should also equal the displacement of the vessel and will show the distribution of the support given by the fluid pressures in relation to the curve of weights at any point in the ship's length.

MOMENT OF INERTIA OF SECTION AT FRAME N.

Assumed neutral axis = 26.5' above base. Actual neutral axis = 1313 = .05' below assumed neutral axis = 25.85' above base line. Moment of inertia about correct neutral axis = 2.684.025 + 7.350 = 696, = 1,381,156 Ft. 2 Sq. In.

Curve of Load.

The curve of loads is obtained by measuring the difference between the curves of weight and buoyancy at the various ordinates and spotting off the excess buoyancy above the base; and the excess weight below their points of intersection with this line will show the waterborne sections, which for calculating purposes are taken as the points of support.

Curve of Shearing Stresses.

This curve is calculated from the foregoing curve of load by taking its area at various ordinates measured from forward aft and plotting these areas off above or below the base line as in the case of the curve of loads, observing that the greatest stresses will be opposite the points of support (or waterborne sections). A curve run through the foregoing spots will show the shearing stresses graphically.

Curve of Bending Moments.

As the bending moment at any section in the length of a ship is equal to the algebraic sum of the shearing stresses in relation to either end, it is evident that a curve of bending moments may be obtained from these stresses and plotted off as was done for the shearing curve from the curve of loads, observing that the maxinum and minimum bending moments will be coincident with the points of support.

To apply similar curves and the data constituting them to the determination of the stresses experienced by a ship amongst waves, it is usual to take the two extreme bending moments to which a vessel is subjected, viz.: (1) hogging on the crest of a wave, and (2) sagging in the trough, and to construct a trochoid wave of such form as will give the same displacement of immersed body (in both cases) as obtained in smooth water. The curves are then calculated as explained in the foregoing, taking the height of wave as being $\frac{1}{20}$ of the length.

The subjoined table shows a specimen calculation of the moment of inertia of the sections, observing that although the rivets in this case are neglected for compression, it would probably be somewhat more accurate to include them.

Unless in exceptional cases it will be found sufficiently approximative for comparative purposes to multiply the displacement of the proposed vessel by one-thirtieth to one thirty-fifth of the length when the product will equal the maximum bending moment, as

 $\frac{L \times D}{35}$ = maximum bending moment,

and the minimum tension on sheerstrake equals

Maximum bending moment × Neutral axis below sheerstrake

Total moment of inertia

Tension stress per square inch. The compression on the bottom plating is similarly computed, substituting the distance of neutral axis above keel for "below sheerstrake."

The value of the maximum tensile strength per square inch of section varies of course with the size and proportions of vessels. A suitable value for vessels of wholesome proportions built to any of the great classification societies' rules is about 2 tons per square inch in small vessels to about 9 in the largest liners, taking the comparative method of calculating the bending moment given above.

It will be evident from an examination of the table showing a specimen calculation of the moment of inertia of a ship's cross section, that the further the sectional area of the ship is arranged from the neutral axis, the greater will be the moment of resistance to bending. It is in recognition of this geometrical quality that the upper deck in 3-deck and other ships is made the strength deck, and that the keel plate and garboards are thickened as well as the sheerstrake and stringer being increased at that level, in addition to reinforcing the bilge; for, with a ship rolling and pitching, it must often happen that the greatest bending moments will frequently be exerted at the bilge and upper deck gunwale. By making the shelter deck in 3-deck vessels the "strength deck," a great increase in the strength of these ships has been made in recent years, as demonstrated by actual practice, steamers of this class being now practically "4-deckers" from a strength point of view.

RESISTANCE OF SHIPS.

The Admiralty Coefficient.

The amount of power required to propel a vessel at a given speed is generally computed by (1) the Admiralty Coefficient formula, or (2) a formula based on the ship's actual resistance, the former being purely empirical and requiring great judgment and practice in the selection of the coefficient, and the other founded on scientific experimental data and theories which have acquired confirmatory proof amounting to law, since they were first enunciated by William Froude. The following notes on resistance are taken principally from the papers by this eminent investigator, and from the later work of Middendorf, Taylor, and others.

The Admiralty Coefficient (C) is calculated from the results of actual trials, and is based on the false assumptions that the area of wetted surface (S) for similar ships is proportional to the $\frac{3}{4}$ power of the displacement $(D^{\frac{3}{4}})$, and that the resistance (R) plus the propulsive coefficient (E, H.P.) varies as the cube of the speed (V^3) . From this we get the well-known formula:

I.H.P.
$$\equiv \frac{D^{\frac{2}{3}} \times V^{8}}{C}$$
,

and for the speed with a stated I.H.P.,

$$V^8 = \frac{C \times I.H.P.}{D^{\frac{2}{3}}}.$$

Therefore the coefficient:

$$C = \frac{D^{\frac{2}{3}} \times V^{8}}{\text{I.H.P.}}.$$

It will be obvious that these coefficients must cover a wide range of values, hence the difficulty of their application by the inexperienced. For this reason we append a table of values in vessels of greatly divergent types. It should, however, be noted that for vessels of similar form but different lengths, the coefficient will show great disparity, and for vessels of similar form and length but different draught, there will likewise be much dissimilarity in the coefficient. In the selection of this coefficient it should also

be remembered that the class of steamer to which it is applied must be similar not only in form, but in type of engine as well, and of corresponding speed. This does not necessarily mean the same speed, as will be explained later.

Table of Admiralty Coefficients.

FROUDE'S LAW OF COMPARISON.

As the result of experiments with models and full sized ships Froude discovered that there was great resemblance between their "curves of resistance," i.e., a curve plotted off with a scale of knots as abscisse, and the pounds resistance to towing as ordinates. See Fig. 51.

To test this, however, it is necessary to apply the Law of

Comparison, which he thus states:—

"If the ship be D times the dimension of the model and at the speeds V_1, V_2, V_3, \dots the measured resistances of the model

To the speeds of model and ship thus related, he applied the term "corresponding speeds." This law expresses the resistance due to surface friction, plus wavemaking resistance, the former being commonly referred to as skin resistance and the other as residuary resistance, embracing as it does, the resistance caused

by the motion of the waves and the drag of dead water eddies, such as are formed at abrupt endings to bossings, the siding of stern posts and in the wake of propeller struts. The skin resistance is proportional to the area of wetted surface, and is responsible for almost the total resistance up to about 8 knots speed. Beyond this speed the total resistance increases rapidly, showing the effect of the residuary resistance. This will be more readily understood, when we recollect that the wave undulations progressively increase in height with increases in speed, and that the crests of these waves are accountable for about 95 per cent of the total residuary resistance, the remaining 5 per cent, as already stated, being due to eddies, etc. Referring to the diagram here reproduced, showing curves of residuary and skin resistances, "the graduated undulations in the residuary resistance curve are due to quasihydrostatic pressure against the after-body, corresponding with the variations in its position with reference to the phases of the train of waves comprising the wave line profile, there being a comparative excess of pressure (causing a forward force or diminution

of resistance) when the after-body is opposite a crest, and the reverse when it is opposite a trough. Their spacing is uniform at a uniform speed, because waves of given speed have always the same length; it is more open at the higher speeds, because waves are longer the higher their speed; their amplitude is greater at

the higher speeds, because the waves made by the ship are higher; and their amplitude diminishes with increased length of middle body, because the wave system by diffusing itself transversely loses its height."

Froude found that, at the lower speeds, two ships, one 200 ft. and the other 240 ft. in length, had the same residuary resistance; the difference in the larger vessel was simply due to its increase of skin friction due to the greater wetted surface. At 13.15 knots, however, the 240-foot vessel had the lesser total resistance of the two. owing to her position on the residuary resistance curve coming in a hollow; the consequent diminution in this resistance was greater than her increase of skin friction.

The resistance depends on the relative placing of the after-body and the wave system, and the length spacing of the wave system depends on the speed, therefore the position of after-bodies, which is specially favorable at some given speed, may be specially unfavorable at a higher speed, and at a higher speed still may be favorable again.

This it is which explains the economy with which some vessels attain certain speed whilst others of almost identical form, but slight variation in length, fall short of the others' performance.

To apply the investigations of Froude to actual ships, it is usual to make a model of the proposed ship and run it in a tank, and from the data obtained apply the law of comparison. For example, if a model be made of a liner 700 feet long on a scale of 1 inch to the foot, and the required speed of the ship be 24 knots, at what speed will the model require to be run to correspond with the desired velocity? "In comparing similar ships, or ships with models, the speed must be proportional to the square root of their linear dimensions."

Therefore the model will be

$$\frac{700 \text{ feet}}{\frac{1}{8} \text{ inch}} = 87\frac{1}{2} \text{ inches,}$$

or 7 feet 31 inches, and the ratio of linear dimensions,

$$\frac{700 \text{ feet}}{7.29} = 96$$

and speed corresponding to 24 knots,

$$24 \div \sqrt{96} = 2.45 \text{ knots.}$$

In like manner, if we are working from the known speed of another ship, say, of 600 feet length, then:

$$\frac{790}{600} = 1.16$$
 ratio of linear dimensions,

and

 $24 \div \sqrt{1.16} = 25.8$ knots, corresponding speed of the 600-foot boat.

APPLICATION OF FROUDE'S LAW.

It is, however, in dealing with data derived from trial performances that the law of comparison is invaluable to those having the responsibility of powering ships. For, given the trial data of the ships, we may apply this to other vessels of similar form to obtain the I.H.P. necessary to drive them at a stated speed. Of course. we assume that the efficiency of the engines, boilers and propellers are equal in both cases, otherwise that their coefficients of efficiency are the same. So that when we know the displacement, power, and speed of a given ship represented by D, P, and V, and it is required to estimate the I.H.P. from a proposed vessel of like form of D_1 , P_1 , and V_1 , then,

(1)

and

$$(2) V_1 = \left(\frac{D_1}{D}\right)^{\frac{1}{6}} V.$$

Substituting values,

(1)
$$P_1 = \left(\frac{32,000}{17,878}\right)^{\frac{1}{6}} \times 29,246$$

= 58,000 I.H.P.
(2) $V_1 = \left(\frac{32,000}{17,878}\right)^{\frac{1}{6}} \times 22.1$
= 24.4 knots.

(2)
$$V_1 = \begin{pmatrix} 32,000 \\ 17,878 \end{pmatrix}^{\frac{1}{6}} \times 22.1$$

= 24.4 knots.

We may also run a speed curve of the known vessel, where progressive runs have been made, as shown in Fig. 53, and from this deduce the proposed vessel's corresponding curve with the aid of the formula given.

The curve illustrated is that of a 56-ft. vedette pinnace, and it is proposed to deduce the power curve of a 21 knot speed launch from it, being a type of similar form.

> Displacement of vedette. . . . Displacement of speed launch . . 22.50 tons.

The corresponding length L_1 of the speed launch would be obtained from the length of the vedette and the ratio of the displacements.

$$\left(\frac{D_1}{D}\right)^{\frac{1}{3}} \times L = \left(\frac{22.50}{13.75}\right)^{\frac{1}{3}} \times 56 \text{ feet} = 66 \text{ feet.}$$

Corresponding speed,
$$\left(\frac{D_1}{\overline{D}}\right)^{\frac{1}{6}} V = \left(\frac{22.50}{13.75}\right)^{\frac{1}{6}} \times 19.25 = 20.85 \text{ knots.}$$

So that after the derived curve has been plotted from the spots calculated as above for various speeds, it must be continued in the same contour until it is opposite the 21-knot ordinate, when the required power may be read off.

STANDARD CURVES OF POWERS.

Taylor in his "Resistance of Ships" advocates the adoption of a "standard" displacement in applying the Law of Comparison, to which all trial particulars should be reduced, and for this purpose takes 10,000 tons as a basis, giving tables of factors to facilitate the reduction of the speed and power data possessed, to this standard displacement.

He makes each curve cover a range of one knot, after the manner shown on Fig. 54. As an example of the method employed in estimating the indicated horse power by the aid of these standard curves and tables, let us postulate that the power is required for a proposed ship of:

Length					440 feet.
Breadth					48 feet.
Draught					19.5 feet.
Displacem	ent				7,000 tons.
Coefficient	, δ				.595.
Speed	•				18½ knots.

Then to reduce 10,000 tons displacement, dimension, speed, and power factors are calculated.

i

In the above case these are 1.126, 1.061, and 1.517 respectively,

Length $\times 1.126 = 495.44$ feet. Breadth $\times 1.126 = 54.04$ feet. Draught $\times 1.126 = 21.96$ feet. Speed $\times 1.061 = 19.63$ knots.

SPEED AND POWER CURVE

From the diagram shown we find that the "Umbria" at 19.63 knots took 13,000 I.H.P. at 10,000 tons standard displacement, and this divided by the power factor 1.517, will give the I.H.P. required, viz.:

$$\frac{13,000}{1.517}$$
 = 8,570 I.H.P.

Any one may prepare a set of these standard curves, making each one cover a range of one knot, from his own trial data.

These will be found very useful, as of the many methods.

employed to estimate horse power, this is probably one of the most reliable, besides being easy of application. Of course, to do this one must be possessed of the requisite data and the judgment to know how to apply it.

In conjunction with the curves, tables should also be calculated for the dimension, speed, and power factors for graduated dis-

placements as follows:

The dimension factor is the ratio of the linear dimensions, as:

Ratio of displacement,
$$\frac{10,000}{7,000} = 1.43$$
;

therefore, dimension factor

$$l = \sqrt[3]{1.43} = 1.126$$

for 7,000 tons displacement.

Speed factor =
$$\left(\frac{10,000}{7,000}\right)^{\frac{1}{6}} = 1.061$$
,
Power factor = $\frac{10,000}{7,000} \times 1.061 = 1.517$.

and

I.H.P. by Independent Method.

Where the type of vessel is abnormal, the speed excessive, or sufficient data to which to apply the comparative method is not possessed, the effective horse power should be calculated in detail from the skin and wave resistances, and by the selection of a suitable efficiency coefficient for the machinery, the Indicated Horse Power may be computed with great accuracy. For this purpose it is necessary to know the wetted surface, and this may be figured with the aid of either of the tables given on p. 98.

The wetted surface determined, this area must be multiplied by the coefficient of friction due to the particular surface which will give the skin friction, and this in turn multiplied by the power necessary to overcome one pound resistance at one knot (.0030707 V) by the 1.83 power of the velocity required, will give the E.H.P. for skin resistance. Otherwise stated.

Skin resistance power = $f.S...00307 V^{2.88} = E_s.$

To this must be added the power for residuary or wave-making resistance E_w .

Wave resistance power = .00307 $bV^5 = E_w$.

Then these two combined give us the E.H.P. for the total resistance, from which the I.H.P. may be determined by taking a suitable coefficient of efficiency.

It should be stated that "b" ranges from .35 in swift, narrow vessels, to .55 in full, slow vessels.

Least Resistance by Middendorf's Method 271

Substituting values and applying them to the determination of the I.H.P. required for the 440-ft. steamer dealt with on p. 189, we have.

Wetted surface = 26,600 sq. ft. = S.

Coefficient of friction "f" = .009.

Power per pound of resistance at one knot = .00307 V.

Percentage of efficiency = 60% of I.H.P.

Speed in knots V = 18.5.

Coefficient b = .35. Then, $E_a = .0$

 $E_4 = .009 \times 26,600 \times .00307 \ V^2.88$

= 2,830 E.H.P.

And,

$$E_w = .00307 \times .35 V^5$$

= 2,330 E.H.P.

The addition of the skin and wave resistance powers gives us the total effective horse power.

$$E.H.P. = 2,830 + 2,330 = 5,160$$

and the indicated horse power at 60% efficiency = 8,600 I.H.P., being a similar result to that obtained by the comparative method.

appended is a table giving the value of these angles for various speeds and lengths of vessels obtained from actual well-known ships of the best form.

On the construction lines of the body plan and profile, a mean water line is drawn half way between keel and load line, as shown

at $rac{D}{2}\cdot$

By referring to the table of angles, a is selected for the length of vessel being designed and the tangent of the same spotted on the half-breadth plan. This will give the outline of the mean water plane.

Two diagonals, D and D_1 , are struck in on the after body plan, the former intersecting the centre line at half the draught, as well as the base line at a distance equal to the half-breadth of the ship, and D_1 intersecting the load water plane at centre line as well as the half moulded breadth construction line at the mean water line height, as shown in Fig. 55.

The angles β and θ are obtained from the table and transferred to the half-breadth plan representing the half planes of D and D_1 respectively.

SECTION II.

STRENGTH OF MATERIALS.

CHAPTER I.

STRESSES.

It is by the application of the known strengths, as derived by experiment, of the various materials used in shipbuilding to the physical properties possessed by their geometrical sections that we are enabled to calculate with accuracy the loads they will bear with a predetermined margin of safety when subjected to either of the four simple stresses of tension, compression, shearing and torsion.

Ultimate Strength is the direct stress producing rupture of the material.

Working Load is the stress applied in practice, and its ratio to the ultimate strength varies with the nature of the stresses applied, viz.: (1) tension with a dead load; (2) tension with a live load, or (3) a live load working alternately in opposite directions (see Table).

Many of the fittings in shipwork come under the third category, as in rudders, derricks, etc. In derricks the inertia of the load has not only to be overcome, but also the jarring and surging. For this reason a very common factor of safety for these details is ten times the ultimate strength.

Proof Strength is the test load to which cranes, davits, derricks, chains, cables, etc. are subjected, and is usually a multiple of the working load or ultimate strength. Careful measurements should be taken before applying this load, and these checked after the load has been removed, to discover, if any, the amount of permanent set.

Stress and Strain.—Stress is the measure of the internal force or resistance in a bar due to the load applied tending to produce

deformation, and strain is the alteration of form due to the stress. So that the relationship between these two terms really is one of cause and effect, although in general the terms are erroneously used synonymously.

Stress is measured by weight and strain in inches, or as a percentage of the length of the bar or member strained. Thus, we say that a 5-foot bar is subjected to a tensile stress of 20 tons, producing a strain of \(\frac{1}{2}\) inch per foot (elongation being \(\frac{3}{2}\) inch) or 1.04 per cent of the bar's length.

Tensile Stress.—If two equal forces acting in opposite directions, away from each other, be applied to a bar, they will tend to stretch it, thus producing a tensile strain.

Compressive Stress.—Should, however, the forces act towards one another they will produce a compressive strain.

Shearing Stress. — When two forces acting in opposite directions are exerted through the cross section of a pin or rivet connecting two flat bars, the pin is subjected to single shear. If, however, another similar bar be connected enclosing either of the other bars, then the pin or rivet will be in double shear, and may be reduced by half its original sectional area.

Bending or Transverse Stress.—Bending stresses are imposed on beams when they are loaded or forces exerted on them, although more correctly, tensile, compressive and shearing stresses are at work simultaneously on the top, bottom and abutments respectively.

Torsional Stress is encountered mostly in shafting and in the rudder stocks of ships. In the latter case it consists of twisting stresses acting alternately in opposite directions, requiring a much larger margin of safety than necessary with any of the other stresses named.

Resilience. — This term is applied to the amount of work done by compressing or extending a bar and multiplying the length of such compression or extension by the load which produced it.

Elasticity is the property which substances possess of returning to their original size and shape after straining. In tension materials increase in length and decrease under compressive stresses, and within certain limits this lengthening or shortening is proportional to the stress applied. From this it is evident that this quality is more important than even the strength of the material in tension or compression.

Modulus of Elasticity. — The amount of this proportional variation of the weight applied and the alteration in length of the

bar is known as the modulus of elasticity, and may also be expressed as the tensile force, which, when applied, will double the bar's length, and of course may be different in the same material when subjected to tension, compression or shear.

Permanent Set. — If a bar be extended or contracted by the application of a load beyond its elastic limit, it is said to have permanent set. This would take place in mild steel if a load of 17 tons per square inch of section were exceeded.

Dı	STAN	CE3.		AREA.	N	IOMENTS
s_1	=	4.40	×	2.04	=	39.49
S_2	=	1.75	×	1.48	=	4.73
S_8	=	2.00	×	1.64	=	6.56
S_4	=	3.75	×	2.44	=	34.30
Mo	ment	of In	ertia	ιI	=	85.08
Sec	tion	Moduli	us	$Z=\frac{8}{F}$	5.08 5.15	= 16.5.

The Moment of Inertia of a section or body is a mathematical quantity used to calculate the strength of materials, and is taken relatively to the neutral axis or centre of gravity of the section. If the section of a bulb tee beam, as shown in Fig. 56, be centrally loaded on top, the fibres above the line xy (neutral axis) will be compressed, and those below extended, and consequently the arc formed by the table of the beam will be shorter, and that formed by the bulb longer, than the arc through the line NS,

which will be exactly the same length as the original dimension of the beam before the application of the load, the lamined through this axis being neither in compression nor tension, and are therefore known as the neutral surface of the beam. Hence, if we take very small areas at known distances from the neutral axis to their centres of gravity and multiply these areas by the square of their distances above or below this line, we shall have by adding the products together the moments of inertia (I) of the section; and again by dividing this moment by the distance of the most extreme fibre we shall get the quantity known as the section modulus.

In the example given the result is fairly accurate, although a more absolute result may be obtained by greater subdivision of the areas. This, however, is not necessary for ordinary calculations.

The value of the section modulus depends entirely on the geometrical form of the section. The material of which the beam is made and its ultimate strength known and divided by the factor This stress of safety selected, gives us the safe limiting stress. multiplied by the section modulus produces the moment of resistance of the beam. In the example given let the beam be of steel of 60,000 lbs, ultimate strength and the factor of safety 5, we then have 60000 = 12,000 lbs, safe limiting stress, and section $modulus = 16.5 \times 12.000 lbs. = 198.000 lbs. moment of resistance.$ Suppose then that this were a 12-foot boat skid beam fixed at both ends and loaded at centre, what weight of steam pinnace would it safely support? The maximum bending moment on a beam so loaded would be 1 WL where W is the weight and L the length between points of support. Equating this bending moment with the moment of resistance, we have

$$\frac{SZ}{5} = \frac{WL}{8};$$

$$W = 11,000 \text{ lbs.}$$

then

Where the figure or section is symmetrical about its centre of gravity the I and other elements may be readily figured from the

appended Table of Elements of Usual Sections.

Radius of Gyration. — The radius of gyration is that fundamental property of a section used in determining the strength of pillars and struts, and its square or r^2 about a given axis is equal to the moment of inertia of the surface about the axis divided by the area, therefore the radius of gyration

$$r = \sqrt{\frac{\overline{\text{inertia}}}{\text{area}}}$$

USE OF THE TABLE OF ELEMENTS OF CIRCULAR SECTIONS.

In calculating the scantlings of masts, derricks, kingposts, rudders, shafting, and details generally, where circular sections are employed, the Table of Elements will be found very convenient and time-saving, as, having determined on a thickness or a diameter to which it is decided to work, the appropriate formulæ for the various elements may be read off with facility.

In the first column is given the ratio of internal to external diameter. It is required to find the elements of a hollow section with an outside diameter D=5 inches and an internal diameter d=8 D=4 inches, or $5'' \times \frac{1}{4}''$ thick.

Column 2 gives the sectional area coefficient of the pipe, viz., $.2826 \times D^2 = 7.065$ square inches.

Similarly the coefficient for the moment of inertia, I, is found in the third column to be .02899 by the fourth power of the diameter D, or .02899 \times 625 = 18.118 = I.

By the fourth column we get the coefficient for the square of the least radius of gyration as .1026 $D^2 = .1026 \times 25 = 2.665$, and in the following or fifth column the radius of gyration = .32 $D = .32 \times 5'' = 1.6$.

For the modulus of resistance of the section, or I/y, the coefficient for the pipe with a ratio of .8 D is

$$.05798 D^3 = .05798 \times 125 = 7.247$$

The torsional modulus of resistance is

$$.11595 D^3 = .11595 \times 125 = 14.493.$$

If it be required to select a diameter of hollow or solid circular section for a given moment of inertia, or, having obtained a diameter, it is found advisable to amend the same to another diameter giving the same I, then the increase or decrease of thickness may be readily computed with the aid of column 8, and in a like manner the sectional area for a constant moment of inertia is calculated by the coefficients in the following column.

The last two columns give, similarly, the diameters and areas for a constant moment of resistance.

Inversely we may calculate the diameter of a bar or tube equal to a given moment of inertia, or moment of resistance, or radius of gyration, etc. For example, the diameter is required of a tubular section which shall equal a moment of inertia of 12. It is proposed to make the pipe relatively thin; therefore we select a ratio of d/D = .90 per column one, from which we get an I coefficient = .01689; therefore,

$$D = \sqrt[4]{\frac{I}{.01689}} = \sqrt[4]{\frac{12}{.01689}} = \sqrt[4]{710}$$

= 5.14 inches outside diameter × 1 inch thick (fully).

CHAPTER II.

STRENGTH OF COLUMNS.

JOHNSON'S FORMULA.

The accompanying table of strengths of wrought iron columns is based on the "straight line" formula proposed by Johnson and generally used in America. The value of the constant K is deduced by making the straight line tangent to the curve of Euler's formula.

$$P = S - k \frac{L}{r}.$$

Where, P = Ultimate compressive unit stress.

S = Maximum tensile unit stress.

k = A constant whose value depends on the condition of the ends, viz., fixed, flat, hinged or round.

L =Length of column in feet.

r = Least radius of gyration.

This formula may be readily memorized for wrought iron columns, thus:—

Ultimate unit stress $P = 52{,}500 - 2700 \frac{L}{r}$, on which basis the table has been calculated.

EXAMPLE. — It is required to find the safe load with a factor of safety of 5 for a hollow wrought-steel strut or column with a length of 46 feet, mean diameter 20 inches and one-half inch thick.

$$r = 20 \times .35 = 7.$$
 $\frac{L}{r} = \frac{46}{7} = 6.57.$

P (from table) = 6,900 lbs.

Area of column = circ. $\times t = 62.8 \times .5 = 31.4 \square''$

Safe Load W = 6,900 lbs. $\times 31.40 \, \square'' = 216,660$ lbs.

Or, if it be required to find the thickness t of the column in the foregoing example, the load being 216,660 lbs.

$$r = 7.$$
 $\frac{L}{r} = 6.57.$
 $P = 6,900 \text{ lbs. (from table)}.$

Area =
$$\frac{216,660}{6,900}$$
 = 31.4 \square ".
 $t = \frac{\text{Area}}{\text{Circ.}} = \frac{31.4}{62.8} = .5$ inch.

Values of r for various sections.

When

$$b=\frac{D}{10}$$

$$r = .32 D$$

Fig. 96.

$$t=rac{D}{8}$$

$$t = \frac{D}{8},$$
 $r = .313 D.$
 $t = \frac{D}{6},$ $r = .301 D.$

$$t=\frac{L}{6}$$

$$r = .301 D$$

$$t=\frac{L}{4}$$

$$r = .279 D$$

(See Table of Elements of Circular Sections.)

Least radius of gyration = $\frac{D}{4}$.

Fig. 97.

Rectangle or square r = .289 D.

Equal sided angle bar $r = \frac{D}{5}$.

Fig. 99.

$$r = .4 D$$

$$r = \frac{3}{8} D.$$

$$r = \frac{1}{4} B.$$

PHYSICAL PROPERTIES OF TIMBER.

The physical properties of timber, given hereafter, are derived largely from the recent experiments of the Forestry Division, United States Department of Agriculture, which form the most complete and systematic series on record. The following general conclusions seem to be demonstrated:

1. That bleeding (the experiments were made on long-leaf yellow pine) has no material effect on the strength of timber, the flexibility is slightly increased, but the bled timber will probably

endure exposure to the weather as well as the other.

2. That moisture reduces the strength of timber, whether that moisture be the sap, or water absorbed after seasoning. In general, seasoned timber, or with not more than 12 per cent. moisture, is from 75 per cent. to 100 per cent. stronger than green timber.

3. When artificially dried, timber contains a uniform percentage of moisture throughout, a condition requiring months or even

years to attain in air-dried heavy timber.

When kiln-dried at usual temperatures, wood shows no loss of strength compared with air-dried timber of the same percentage of moisture. The effect of very high temperatures and pressures (as used in vulcanizing) is lower strengths than when air-dried.

4. Large timbers are equal in strength per square inch of section, tested every way, to small timbers, provided they are equally sound and contain the same percentage of moisture.

5. The tests seem to indicate that the strength of woods of uniform structure increases with the specific gravity irrespective of species; i.e., in general, the heaviest wood is the strongest. Oak seems not to belong to the list of woods to which this general remark applies.

The data on properties of timbers must be used with considerable judgment and caution. Seasoned wood will gain weight, to the extent of 5 to 15 per cent., if exposed to the weather, and this excess will be reduced if the wood is kept a week in a warm dry place. Some of the individual tests made by the United States Forestry Division varied considerably from the mean values given in the table. In the case of tension tests, which varied most from the average, a few were as low as 25 per cent., while others reached 190 per cent. of the mean. The elastic limit given in connection with the data from the United States Forestry Division is the relative elastic limit suggested by Professor Johnson, as there is no definite "elastic limit" in timber similar to that in some metals. This relative elastic limit is taken where the rate of deflection is 50 per cent. more than it is under initial loads.

Modulus of ultimate bending is extreme fibre stress on beam at rupture. The modulus of elastic bending is the fibre stress when the rate of deflection is increased 50 per cent. The modulus of

elasticity is derived from transverse tests.

240.5 250.7 258.8

The breaking stress of the iron of which chains are made varies with the diameter of the bar, being less the greater the diameter.

If f= breaking stress of iron in tons per square inch,

and d = diameter of bar in inches,then f = 26.2 - 2.4 d.

then f = 26.2 - 2.4 d. Breaking load of chain in tons = $W = 1.22 d^2 (26.2 - 2.4 d)$.

This formula allows for the bending action, and for the loss of strength due to the weld.

The following table gives values of W for various values of d, calculated by the above formula:

d	W.	d.	W.	d.	W.	d.	W.

SHACKLES.

For most purposes in ship details where shackles are used, it is common practice to order the shackles given in Table of trade shackles, suiting the size to the chain, wire or manila rope that

Fig. 111.

they are linked with. Where, however, special cases arise in dealing with exceptional loads the size of the shackle and pin should be accurately calculated, taking care that the widths between jaws and across the bow are no greater than necessary to take the con-

nections, as these dimensions are considered as the beams support-

ing the load as in the diagram.

The dimensions are required of a shackle to take a working load of 10 tons (22,400 lbs.), with a factor of safety of 6 equal to a unit stress of 10,000 lbs. It is assumed that the pin is shipped in a pad-eye, bearing along its entire length, i.e., the load is distributed. We thus have the case of a beam supported at the ends and uniformly loaded, the maximum bending moment M being $\frac{Wl}{\omega}$. The length l (3") will have previously been determined by the

bearing value given in designing the pad-eye. Then,

$$\frac{Wl}{8} = \frac{22,400 \times 3}{8} = 8,400 \text{ inch-pounds} = M.$$

The moment of resistance of a circular section (the pin) is equal to $\frac{\pi}{20}$ D⁸, therefore the diameter D which will equal this bending moment (M) just figured with a fibre stress of 10,000 lbs. must be,

$$D = \sqrt[3]{\frac{M}{\frac{\pi}{99} \times f}} = \sqrt[3]{\frac{8,400}{.0982 \times 10,000}} = 2.04 \text{ inches.}$$

The diameter of the wire forming the bow at B is calculated in a similar way, noting that the load this time is central, but the ends of the beam being now fixed, we have the same formula for the maximum bending moment, viz., $\frac{Wl_1}{2}$. Assuming that it has been necessary to bow the shackle, "l1" has now been increased to 4 inches, so that

$$\frac{Wl_1}{8} = \frac{22,400 \times 4}{8} = 11,200 \text{ inch-pounds} = M,$$

and applying the formula for a circular section as in the pin, we $\sqrt[3]{\frac{11,200}{0982 \times 10,000}} = 2\frac{1}{4} \text{ inches diameter at } B.$ have

From the diameter B the wire may be tapered to A, where the sectional area need only be such as will resist tension, but it is usual in practice to increase this amount by 25%, owing to the load at times becoming eccentric, thus throwing a greater stress on one leg.

$$\frac{W}{f} = \frac{22,400 \text{ lbs.}}{10,000 \text{ lbs.}} = 2.24 \text{ sq. in.} + 25\% = 2.8 \text{ sq. in.}$$

$$= 1.4 \text{ sq. in. per leg.}$$

$$= 1\frac{3}{2} \text{ in. diameter at } A.$$

The sectional area and dimension C are computed by considering l_2 the length of beam which is now fixed at both ends and uniformly loaded when M is equal to $\frac{W \, l_2}{12}$. The dimensions are calculated as in the foregoing, observing that the resistance is now for a rectangle, and the bending moment will consequently equal

$$\frac{AC^2}{6} \times f$$
.

CHAPTER IV.

STANDARD RIVETING, U. S. NAVY.

- 1. All rivet holes through material 1 inch or more in thickness should be drilled, or if punched should afterwards be reamed to finished size.
- 2. In cases where rivets connect plates of different thickness the size of rivet indicated for the greater thickness with corresponding spacing will be used where strength is required, and that indicated for the lesser thickness where water tightness is a special consideration, always provided the greater thickness is not more than double the lesser.
- 3. Where tap-rivets must be used they should be 1 inch larger than the corresponding ordinary rivets for the same thickness. except taps into heavy castings and forgings such as stem and stern posts, which should be 1 inch larger. Where strength is required, taps should not penetrate less than one diameter, and should penetrate 11 diameters when the thickness of metal will allow it.
- 4. Where the spacing given in Table No. 3 cannot be followed exactly, as will generally be the case, make the spacing a trifle closer (as necessary with heavier plating) and a trifle further apart (as necessary with lighter plating), the division between "heavier" and "lighter" plating coming at 71-pound plates for single riveting; at 15-pound plates for double riveting and at 25-pound plates for treble riveting.

5. Where the above distinctions are considered too complicated for yard work, the general rule will be to space a trifle closer in

all cases, as necessary for equal spacing.

6. Where strength is required in laps and butted connections of plating, with the spacing indicated, single riveting is suitable only for plating under 121 pounds, and double riveting for plating under 25 pounds. For maximum strength in connections of plating above 30 pounds it will generally be found that quadruple riveting is required.

Single Straps.

7. Single butt straps and edge strips, when single or double riveted, should be the same thickness as the plates connected, and where the plates connected are of different thickness, the straps or strips should be of the same thickness as the lighter plate. Single butt straps when treble riveted should be 11 times the thickness of the plates they connect.

Double Butt Straps.

8. Double butt straps should not be used for water-tight work, owing to the difficulty in caulking. They may be used to advantage in conditions requiring great strength but not water-tightness. The thickness of each strap should be ½ the thickness of places connected for double riveted straps, and § the thickness for treble riveted straps. The spacing of rivets in rows should be calculated. Size of rivets for double butt straps as follows:

For plates from 15 to 20 pounds, exclusive, § inch rivets.
" " 20 to 25 " inclusive, ¾ " "
" above 25 pounds, see Table No. 1.

Distance between Rows.

9. Centres of rivets should be placed not less than 1\frac{1}{8} times the diameter from the edges of plates connected. In double and treble riveting for laps and single straps, the distance from centre to centre of rows should not be less than 2\frac{1}{2} diameters; in butt laps and double butt straps the distance between centres of rows should be not less than 3 diameters. (Butt laps should be at least double riveted.) For zigzag riveting the distance between centres of rows should not be less than 1\frac{3}{2} diameters for rivets spaced 4 diameters apart in rows.

† In butts connected by single butt straps alternate rivets may be omitted in the back row of treble riveting when the plating number is 20,000 and under; when above this number, the rivets in the back row are not to be more than 5 to 51 diameters apart from centre to centre. All overlapped butts are to have complete rows of rivets.

* When the rule frame spacing is 26 inches or above, the rivets in the edges of outside plating (forward and aft) are not to exceed 4 diameters apart from centre to centre, and the rivets attaching the outside plating to frames are to be spaced not more than 6 diameters apart from centre

In deep water ballast tanks above the level of inner bottom, and in fore and after peak water ballast tanks, the rivets through frames and outside plating are to be spaced not more than 6 diameters apart from centre to centre.

Before the three-fifths length of a steamer having a tonnage coefficient of .78, or having a full form at the fore part, the rivets in the landing edges of the strakes of plating forming the flat of the bottom to be spaced not more than 4 diameters apart from centre to centre. The rivets in the plating and frames in way of the same to be spaced not more than 5½ diameters apart from centre to centre.

Rivets to be 1 of an inch larger in diameter in the stem, stern frame, and keel, but in no case need these exceed 1½" in diameter, and to be spaced 5 diameters apart from centre to centre. In single screw steamers above 350 feet in length, the after lengths of shell plating are to be connected to the portion of the stern frame below the boss with 3 rows of rivets.

Rivets in side plate rudders to be of not less size than those required for the upper edge of garboard strake amidships, and to be spaced not more than

5 diameters from centre to centre. The rudder plates are to be countersunk and the rivets are to have full heads and points.

Rivets in single plate rudders are to be of not less size than required for attaching the outside plating to the stern frame, and spaced not more than 5 diameters apart from centre to centre. The rivet holes are to be countersunk both in rudder plates and the arms, and the rivets are to have full heads and points.

Rivets in the edges of deck plating are to be spaced not more than 4 to 4 diameters apart from centre to centre.

In single riveted seams one frame rivet is to be fitted through the landing edges at each frame. In double riveted seams one frame rivet is to be fitted through the landing edges at each frame, except where the frames or the edges of the outside plating are joggled when two rivets are to be fitted. In treble riveted seams two frame rivets (the upper and lower) are to be fitted through the landing edges at each frame.

Where the fore and aft flange of the frame does not exceed 3 inches, the rivets attaching the outside plating thereto should not exceed 1 inch in diameter, and where it is 31 inches wide, they should not exceed 1 inch in diameter.

There are to be at least four rivets in each flange of the angle bars between the frames which connect the stringer plates and intercostal plates to the outside plating. Where the frames are spaced less than 29 inches apart, and where the spacing is 29 inches and not more than 32 inches there are to be five rivets in each flange.

The rivets in the beam knees are to be in number and size as required.

The rivets in the vertical angles connecting floors and outside brackets to

margin plates are to be in number and size as required.

The rivets in the connecting straps for web frames and side stringers are to be in number and size as required.

lines are less than double and greater than single shear. Values below and to left of lower zigzag lines are less than single shear.

. .

SECTION III.

DETAILS, STRUCTURAL.

KEELS.

In steel ships the keel is invariably one of the three forms of bar, flat plate or side bar, the first and third being almost entirely su-

perseded by the flat plate type which is on all points a much better method of construction than the others, besides having the great advantage of saving from 6 to 12 inches of draft, thereby increasing the dead weight carrying capacity from about 15 to 1,500 tons respectively on a

given immersion. Bar keels should have no place in modern ship construction, unless when required for rubbing purposes only.

Bar Keels.

These should be made of rolled steel universal bar in preference to the old-fashioned scrap iron forgings and scarphed together in long lengths by right and left-handed scarphs. The scarphs are mostly made nine times the thickness of the bar in length, and the jog, or check, and point should be one fourth the thickness. Scarphs of keel should be close fitting and for that reason must be machined, the connection holes for rivets are drilled, and in addition a few holes, about one third the number of regular ones, should

be drilled of smaller diameter, but countersunk on both sides, for tacking the various lengths together before erecting and riveting the garboard strakes. Care should be taken that these scarphs are shifted well clear of the garboard strake and centre keelson butts and that the joints of scarphs are caulked watertight.

The diameter of the rivets should be in accordance with the requirements of the riveting tables given on p. 260, and staggered as shown. The vertical spacing requires special care in keeping clear of the radius of garboard plate and also the caulking edge of same at bottom, which is raised about half an inch from lower edge of bar. For this reason it is advisable to set off the bar full size, drawing in the flanges of garboards before fixing on centres of rivet holes.

Flat Plate Keels.

Keels of this type are made of a thick plate forming the bottom member of a girder of which the centre keelson is the web. The forms mostly in use are shown by the Figs. 134 and 135. Fig. 136

shows a very efficient and economical form of flat plate keel and centre keelson devised by the author and designed with a structural I section for small and moderate sized vessels with ordinary floor construction. Where a suitable I section is not obtainable the same construction may be retained with advantage with built-up section.

The flat plate keel should always be arranged as an inside strake, as by so doing the keel and its sister member may be laid on the

keel blocks right away without anticipating linering in addition to making a more solid job and saving a small amount of draught. It is a fallacy to place it outside with the intention of disturbing Stems **353**

only one plate in the event of damage—a remote contingency which should not be allowed to interfere with good construction.

Where a doubling is required by the classification societies' rules it will be found advantageous, where practicable, to increase the

plate keel to a sectional area equivalent to that of the keel and doubling, and if double buttstrap be required, the inside one may be fitted in two pieces.

Scantlings and riveting will be as specified or to rule requirements.

At the forward and after ends the keel plate must efficiently incorporate with the stem and stern frame respectively, a short "breeches" plate being usually worked for this purpose. In small con-

struction a "spoon" plate is welded to the bottom of stem bar in lieu of the short plate referred to, and a similar plate of "gutter" form welded to stern frame.

STEMS.

The remarks on bar keels apply equally as regards details to stems. The classification societies' rules allow a reduction in

sectional area at stem heads, but as the practice is now to make the stem from universal rolled bar, it will prove no economy to taper it. The usual method of connecting lower part of stem to keel plate are shown by Fig. 137. In straight stems the profile line should be cambered about $\frac{2}{3}$ " from where it joins the forefoot curve to stem head, to guard against the illusion of the contour line appearing hollow.

STERN FRAME

These frames are mostly forged or cast in steel in one piece for small and moderate sized steamers, and in two or more parts for the larger vessels. As in the case of stems, bar keels, etc., the scantlings are determined from the corresponding numeral of the societies' rules to which the ship is being constructed. The two posts comprising the stern frame, viz., rudder and body posts with the joining arch, are of similar scantlings, but the keel piece connecting the posts at bottom while of the same sectional area as the posts, is flattened out to allow of the keel line being curved upwards to the clump for keel pintle bearing of rudder for protection to the latter in the event of grounding.

Gudgeons are forged on the rudder post of frame from 4 to 5½ feet apart to take the pintles; one, or two in large vessels, being so shaped as to engage the rudder stop at hard-over. This post is connected to the main structure on a deep transom plate clipped to its fore side, and in vessels of over about 300 feet in length the forward or body post must also be carried up and secured in a similar manner. The body post is swelled around the stern tube, having a sectional area through the eye equal to the frame and meeting the post above and below in a fair curve; the spur or keel part of frame must not be too long to facilitate handling, the general rule being about 2½ frame spaces before the body post, where it incorporates with, or scarphs into, the keel as already described.

In steamers over 350 feet length where these frames are of considerable weight, the riveting connecting body post to hood ends of shell plating should be treble below boss and of increased diameter and an addition made to the plating thickness. As in the keels, these holes must be carefully drilled and where scarphs are introduced as in the case of frames of two or more pieces the riveted connection should be developed to equal the bar. It is common to make the contour of body post curvilinear, thus effecting an appreciable saving in weight over the straight line, besides giving a more graceful form.

In small steamers the after or rudder post may be dispensed with, a spur being carried aft from body post to support heel pintle.

For single screw steamers classed to Lloyds the weight of stern frame may be very closely approximated by taking the first numeral to upper deck and multiplying it by 240 for vessels over 300 feet in length, or by 155 for those under this dimension, as first number × 240 = weight in pounds.

RUDDERS.

Some of the more common forms of rudders are shown in Figs. 138 to 143. The stresses to which they are subjected and the

method of determining the diameter of stock has already been fully described.

The single plate rudder, Fig. 138, is the type most commonly adopted in merchant steamers, and is usually built in three parts, viz.: the frame, norman head and plate.

The frame may be either cast or forged, BOLTED COUPLING having arms or stays projecting from the stock on alternate sides of centre line spaced opposite each of the gudgeons, which are from 4' to 5' 6" apart.

The norman head or stock should be forged in iron or steel with a coupling palm at lower end to connect with a similar palm on head of frame. Allowance should be made on this forging for machining a key to lock the norman head to the frame, and in addition turned coupling bolts are fitted with nuts on under side, threads turned off to a thimble point and split pins fitted. These bolts are from one to three inches in diameter in practice. Their size, however, is not important, as the shearing stresses are all taken on the kev. The stock need only be turned in wake of the rudder quadrant where it is sometimes increased in diameter to compensate for cutting the keyway.

The single plate forming the rudder blade is fitted between, and riveted to, the supporting arms, besides engaging a groove cut down the back of rudder stock. Its thickness ranges from about \(\frac{1}{4}'' \) in small steamers to 1\(\frac{1}{4} \) inches in liners.

Braces are formed at the ends of supporting arms which are turned out to take fitted pintles. One (two in large rudders) of these braces must be shaped to act as a stopper when the rudder is put hard-over. The pintles should preferably be fitted.

separately and of the cone type shown in the detail. It is bad practice to forge pintles on the frame, as besides the difficulty of turning them in a lathe they have the disadvantage of not being readily renewable. The best manner of bushing the pintles is a matter of opinion, the simplest and probably the one most favored being to make the bushes of hard steel with a flange to take the tap screws securing them around the eye of the braces. The weight of the rudder in small vessels is taken on a hard steel disc placed in the heel step bearing with a hole through the heel step

for backing it out. In large steamers, however, where the weight of rudder is many tons, the weight should always be taken by a carrier seated inside the counter. Various types of these are shown by engravings 144 to 146. Provision must be made on the back of rudder well clear of water line to fit a jew's harp shackle for securing the emergency chains, which are from thence carried up the counter, being stopped with ratline stuff to tapped eyes spaced about thirty inches apart.

Next in favor to the single plate is the cast steel rudder, Fig. 139, although where only one is being made its cost is against it. For the largest sizes its difficulty of successful manufacture is also to

Its disadvantage, although this is got over by casting it in two or more pieces, see Fig. 140, keying these together and riveting them through coupling flanges. When rudders are designed to be cast in one piece, the ribs which are cast on the blade to act as stays should be of easy section, so as not to interfere more than necessary with the contraction of the casting in cooling.

The oldest method of making the rudder for steel ships is the built type, Fig. 142, which consists of a forged frame having stock, stays, and back piece in one, with two side plates riveted to same

after having the inside filled in with fir coated with tar. Its great objection is the cost of forging, especially for large rudders. It has gone completely out of favor unless for yachts, where its appearance commands its use, and in light craft of the torpedo boat kind where sufficient stiffness would not be obtainable in a single plate without going into a thickness which would make the weight prohibitive. It is also often used with the frame cast in gun metal and the side plates of 16 gauge brass sheet, for wood speed launches, vedettes, pinnaces, etc., although for these craft a cheaper and lighter rudder may be obtained by casting it complete in gun metal or bronze.

Fig. 144.

FIG. 147.

Where the rudder stock enters the vessel, watertightness must be ensured by fitting a trunk having a stuffing box and gland at its top. This latter, however, may be dispensed with where a carrier is arranged for, this being an additional element in favor of the adoption of these supports. Before fixing on the counter dimension of the rudder trunk, care should be taken that ample clearness is given to ship and unship the rudder. It will be seen, therefore, that the hole through the counter is much in excess of the diameter of stock, and if not filled in would be unsightly, be sides allowing a considerable volume of water continually at play inside. It is covered in with a tail plate fitted in halves and secured with hexagon head taps to the counter plating, so as to be easily removable to permit of unshipping the rudder.

Good proportions for such details as pintles, gudgeons, braces, couplings, etc., to meet most requirements are shown in Fig. 147.

PROPELLER STRUTS.

These brackets for supporting the outer end of tail shaft are generally of pear-shaped section as being the form of least resistance. It is usual to cast them in steel, although they are also sometimes built up.

In selecting a suitable area of arm shipbuilders are guided mostly by experience, hence the divergent results seen in practice. The author has therefore devised the formula given on p. 109, in which he has attempted to secure a uniform relationship between the size of these struts and the power transmitted through them.

Where possible the centre of the propeller bracket should be placed on a frame to obtain the maximum of stiffness, and the palms of upper and lower arms may be cast on or connected with angle clips. A web spur is sometimes cast or worked on keel length of stern post to take the palm of lower arm instead of flanging the latter and riveting it through the keel to it, securing independent connection for each strut.

In wake of the upper palm additional stiffening must be worked by fitting a short local doubling on shell and a stringer inside. The number and diameter of palm fastenings should be developed according to the sectional area of the arm, these being in most cases overdone.

The sectional area of arms must not be tapered towards the boss, as, although theoretically considered as a cantilever, this would be rational, it must not be lost sight of that the greatest stresses are borne by the ends of the arms adjoining the boss, and are, besides, alternating ones inducing fatigue.

The engineer will determine the length of boss barrel suitable for bearing and also the finished diameter of the hole, but ample

allowance should be made for boring out to this dimension and also adjusting to centre line of shaft; this is most important when dealing with cast steel, as it provides the opportunity to detect hidden blow holes. A mass of metal should be avoided where the arm swells to meet the boss either by reducing the fillet to a minimum or coring out the metal inside the boss, as otherwise internal stresses will be set up in cooling or dangerous blow holes developed.

In high speed vessels it is important to make the pattern "wind" conforming to the run of the water line, thus obviating the arms being dragged across the stream lines and creating eddies. It is surprising the amount of power absorbed by this resistance when brackets are badly set or not set at all.

SPECTACLE FRAMES.

Spectacle frames have nearly superseded the open A brackets for large merchant vessels. They are enveloped in the hull of the ship, the plating being webbed out and bossed around the shaft for this purpose, as fully explained in the chapter on Design, which see.

Where the plating ends on the arms of these frames a good riveted connection must be made, usually double and increased to treble tap rivets around the boss. Local strengthening must also be fitted in wake of spectacle frames by increasing the deep floors in thickness and doubling the ship's frames in their vicinity.

CASTING AT STERN TUBE

The outboard end of stern tube in vessels fitted with A brackets is supported by and connected to a steel casting or forging. Its function is similar to the boss on body post of a single screw steamer.

In large steamers it is usual to extend this casting over two frames in length to give additional support, as shown in Fig. 148, but in small vessels the tube end support need only be from 2 to 4 inches thick, and shaped like Fig. 149. Usually a watertight bulkhead is fitted at the forward and after ends of the stern-tube, the former one being bossed and spectacled at the wings in the manner depicted in the detail given.

The inboard palm of the tube end forging is securely riveted to

wing plate of bulkhead, which must be increased in thickness for the heavier riveting necessarily employed for this purpose.

FRAMING.

In ships having ordinary floors the frames are invariably run in one piece from centre line to gunwale, and where channel bars or bulb angles are employed with this construction, the floor plates may be reduced in consideration of the excess strength given in their wake. Vessels having a double bottom on the cellular system need only have angle frames on the deep floors with flanges sufficient to take the size of riveting required. Forward in the flat of bottom in full vessels these should be doubled inside tank and in addition local fore and aft stiffening fitted to reënforce against "pounding." Where vessels are classed, as they mostly are, the scantlings of the frames are obtained from the rules of the classification bureau. The angle bars of which they are made is always one with unequal legs, the larger flange standing vertically to the shell plating to obtain the greatest section modulus in the direction of the pressure.

Where frames are cut at margin plates of inner bottoms or at water tight flats. efficient bracket plates of such dimensions as will permit of riveting to develop the strength of frame bars should be fitted. See Fig. 153 and 159. In wake of flats where bracket knees are objected to on account of the broken stowage created, or their interference with cabin arrangements, the framing may be continuous and smithed angle collars or pressed plate chocks fitted around them to ensure water tightness as in Fig. 150. For simplicity in forming collars, frame and reverse bar or channel section, the reverse bar, or flange, may be cut off and the frame bar doubled for a short distance above and below the flat as compensation as in Fig.

Where main frames are stopped at weather deck when the bridge house or superstructure requires a bar of smaller section, the connection between weather deck stringer and frame may be completed with a spirketting plate in lieu of

Fig. 151.

would encroach on the berthing space, as shown at Figs. 152 and 153.

The inboard member of a ship's framing, called the reverse bar, whose functions are to provide a flange whereon to fasten the ceiling, or lining, and to give the necessarv section modulus by adding area at a point subjected to corrosion and rough treatment, is commonly made of angle section or by the employment of channel bar for the framing. In steamers. however, under about 100 feet. it will be found economical. besides being good construction to omit the reverse bar altogether and increase the sided flange of frame angle to give an equivalent

I. A saving in material, riveting and bending will thus be effected. In light vessels where weight must be cut down with-

Fig. 154.

out encroaching on the strength, the maximum section modulus may be obtained for a given depth of web by employing two bars of such dimension of leg as will just give the requisite size of lap to take the proper riveting, as in Fig. 154.

The practice in vogue for many years of placing the frame and reverse bars back to back has given place to that of fitting them bosom to bosom where deep framing is adopted, as by this

method the beam knees can be fitted without linering in wake of reverse frames.

FLOORS.

The deep plates riveted to the bottom framing of ships and known as the floors, are placed there to resist the transverse stresses to which the bottom plating is subjected, due to the great water presure externally applied, and the inside forces created by the weight of the structure and cargo.

Ordinarily in ships without an inner bottom these are of a size based upon the breadth and depth of the vessel and carried in a fair line up the bilge to a height equal to twice the centre line dimension as in Fig. 155. It will be seen that this contour at the bilge necessitates furnacing the tail ends to bend them to the required curve, a costly and therefore an objectionable feature. For this reason ordinary floors should be increased in their sided areas and carried straight across, striking the bilge at a point somewhat lower down than with the curved floor. This method permits of the floor being flanged across top in lieu of fitting a reverse bar,

Floors 367

although some of the classification bureau penalize flanging plates to the extent of adding one-twentieth to their thickness; this need not, however, be made unless where specifically required and for that reason cheaper, lighter, and equally efficient construction will be obtained.

In small freight steamers and barges a strong and inexpensive floor is obtained by using structural channel section thus elimi-

nating the riveting to frame and reverse bar altogether.

Floors in inner bottoms are almost entirely fitted as deep solid plates in one piece from centre vertical keel to margin plate, lightened with large manholes to cut out superfluous material and provide access to the various compartments into which the bottom is sub-divided by the floors and intercostal girders. Deep floors should be lapped to the bottom frames just sufficient to take the riveting. In wake of watertight bulkheads or at ends of ballast

tanks where the floors are watertight, no holes whatever must be cut in them. The margin plate of inner bottom being continuous, is connected to the main frame by a large bracket plate or tail piece, and by double angles having a specified number of rivets and a gusset plate at top, or in the largest vessels a continuous stringer. The connection to the siding flange of main frame is by lap of sufficient width to take the riveting. See Figs. 157 and 158.

At the ends of the vessel where the waterline at top of floor would necessarily be comparatively narrow, increased depth must be given to provide compensatory area and also ensure sufficient width to clip the centre keelson to floors. In the fore peak this additional depth is required to resist buckling and panting, and generally to give local stiffening at a part subjected to unusual stresses. It is also necessary to increase the floors considerably in depth in after-peak, owing to the severe stresses encountered when the propeller "races" and the stern is in air.

INNER BOTTOM.

Double bottoms are fitted in vessels to enable them to safely make voyages "in ballast" without incurring heavy expenses by loading and discharging dry ballast. For this purpose the floors are plated over, forming an inner bottom enclosing with the ship's plating a pontoon in which to carry sea water as ballast, an expeditious, inexpensive and clean method of doing so. Two or three methods of fitting water bottoms are met with in practice, but as these have given way to the cellular system, it is unnecessary to describe them. This method consists in the subdivision of the space formed by the pontoon referred to, into a great number of small compartments or cells bounded by the floors in a fore and aft direction and transversely by intercostal girder plates, making these cells approximately two feet by four feet, respectively, by

the depth of water bottom. The water passes freely between these cells as the floors and intercostals are pierced with access holes unless where mentioned hereafter. The cells are arranged in separate groups or compartments enclosed by the centre vertical girder, watertight floors and the margin plate, this larger subdivision being neces-

sary for trimming and filling purposes, as otherwise a large surface of free water would be highly dangerous in certain conditions.

As mentioned, the centre vertical plate is continuous fore and aft, fitted usually watertight and connected top and bottom to inner plating and plate keel with suitable angle bars. No holes whatever should therefore be cut through vertical keel plate, and although it is not necessary to caulk it in way of ballast tanks, the riveting should be of watertight pitch. Of course where fresh water is carried this longitudinal girder must be properly caulked. At the ends of the vessel where fore and aft subdivision is unnecessary the centre plate may have access manholes as in the floors.

The butt connections are preferably formed with double butt straps, each of about two-thirds the thickness of plate. Through butts should not be used here, as besides interfering with the passage of the fore and aft angles they only give single shear value to the riveted con-

nection.

The outboard side of the inner bottom, or margin plate, is fitted to shell by means of a continuous angle bar, the main frames of the ship being cut for that purpose. At the top this plate is flanged in board to take the inner bottom plating as shown in Fig. 157.

ing as shown in Fig. 157. The butts of margin plate are covered with single strap fitted on the inside of tank.

This plate may also be fitted with advantage as shown in Fig. 158 devised by the author, which consists in flanging the plate outboard, a shape that the plate will take more naturally where

there is curvature in a fore and aft direction. This outboard flange will also permit of machine riveting and connecting to the reverse flange or bar on the floor bracket, thus forming a continuous stringer; or, angle section may be substituted for the flange where facilities for bending are not obtainable.

Another method of fitting the margin is illustrated by Fig. 159, where the top plating is carried right out to the shell and flanged upwards to take staggered riveting. Flan-

ging is preferable to fitting an angle bar, as in the latter case difficulty would be experienced in putting in the rivets on the horizontal flange of the bar. It is, however, a cheap method of construction, its principal objection being the broken stowage caused by the brackets connecting frame to inner bottom.

The inner bottom plating will be of such thickness as the classification societies stipulate where the vessel is classed, when it will be found that increased scantling is required under engines and boilers, and of course the centre strake and margin plate will also be thicker than the rest of the plating, owing to the formex being the rider plate member of the girder formed by the centre

vertical keel and keel plate, and the latter being an important factor in the longitudinal strength of the ship. For this reason when arranging the access manholes, these must always be kept clear of the centre strake. A good shift of butts must be arranged for the plating, and these shifted clear of the butts of shell, margin plate and longitudinals.

Where the strakes of inner bottom plating are arranged "in and out," the packing liners to outside strakes should be fitted short,

the unfilled spaces acting as air holes.

The practice of fitting wood ceiling on tank tops is giving way to coating the plating, with tar or bitumastic cement, as this prevents the deterioration that goes on under the wood, besides adding to the stowage capacity. Where, however, wood ceiling is required,

it must be laid on fore and aft bearers and screwed to same and not fastened through tank top. For this reason, i.e., guarding against leakage the heels of the hold pillars are riveted to vertical flange of tee or angle lugs which are first riveted through inner bottom.

In arranging the manholes care should be exercised that they are located in accessible parts of holds and clear of cargo hatches. In holds of ordinary length one each side at each end about quarter the beam outboard will be sufficient, and in long holds an additional one about the middle of the length. In no case as previously pointed out should they go through the centre strake. The best location aft will of course be in tunnel alleyways, and in machinery spaces they should be fixed by the engineers.

This arrangement will contribute to the best circulation of air when the covers are taken off for ventilating purposes. Ample room must be allowed for rim of manhole to clear landings, butts, longitudinal clips, etc.

The shell plating forming the bottom of tanks may be reduced

in thickness in consideration of the extra strength added by this construction, and the broad liners fitted to outside strakes in wake of watertight bulkheads may be replaced by narrow liners at watertight floors in tanks.

To drain the various compartments of the double bottom when the ship is in dry dock, screw plugs of composition are fitted in the garboard strake and a compensating plate riveted around the hole. A detail of such a fitting is shown by Fig. 160. It is usual to fit similar plugs in the trimming tanks at fore and after peaks.

BEAMS.

Beams are fitted at various levels, or decks, to tie the ship together and afford supports whereon to lay the decks to take cargoes. The strength of these will depend therefore on the load as well as the span or breadth of beam, as it will be seen that a weather deck beam need not be as strong as the one under it, and so on—each successive tier taking the accumulated load superimposed.

It is common practice to give all decks a round-up or camber, an expensive practice that is unnecessary unless on the weather deck, and only necessary there in a modified sense to obtain the statutory freeboard or to conform to classification requirements. It is a fallacy to imagine that strength is gained by cambering the beams thus supposedly constructing an arch, as you cannot have a compressed beam without abutments, which the sides of the ship are not. To meet the requirements mentioned above, the weather deck should have the standard camber of one-quarter inch to the

foot of length, thus as beam 40 feet long will have a round-up at centre line of ten inches. This curve may be set off very quickly with the aid of a common slide rule by setting the courser to the required round-up on the first or

top scale and to the half beam on the third scale, when the camber at any desired distance in board of ship's side may be found by moving the courser to the dimension required and reading off on top scale. The reading subtracted from the total camber will give the required round-up. This may also be figured as shown in Fig. 161. The beams are connected to the main.

Beams 375

frames by welded knees or bracket-plates, the latter being much the cheaper and, where appearance is not important, the better method. The depth of these knees is commonly $2\frac{1}{2}$ times the depth of beam if of channel or bulb tee section, and three times the depth if angle bar be used. The thickness should be the same as the beam unless where welded knees are fitted, when it is good practice to increase the plate one-sixteenth to allow for loss in smithing. When dealing with beams conforming to Lloyd's Rules, it should be noted that the bracket knees are regulated in depth and thickness by the size of the bulb plate required by the table, irrespective of the dimensions of the substituted equivalent section of channel, bulb angle, or bulb tee. For example, if the rules require a built beam of bulb plate and angles, the former being $10\frac{1}{2}$ \times $\frac{1}{2}\frac{1}{2}$, and it was decided to fit the equivalent channel bar of 11 \times $3\frac{1}{2}$ \times $\frac{1}{2}$ and it was decided to fit the equivalent channel bar of 11 \times $3\frac{1}{2}$ \times $2\frac{1}{2}$ \times $2\frac{1$

Standard beam knees as used in Navy practice are shown by Figs. 162 to 167. In arranging the riveting in plate knees, the required number is usually specified for classed vessels, and as these are invariably staggered, it is well to locate the first rivet hole as far outboard on the beam, and down on the frame, as practicable. Those in the corner may be treated as common to both arms in

counting the number required.

Where unsheathed steel decks less than $\frac{26}{26}$ " thick are fitted, beams must be fitted on every frame, with stronger beams at ends of cargo hatchways. Where the thickness is $\frac{26}{20}$ or over, the beams may be fitted on alternate frames with half beams on every frame abreast of hatches. When this spacing is adopted, most societies require closer spacing of rivets through deck plating, viz., 5 diameters apart as against 7 to 8 diameters with the closer spaced beams, so that it is doubtful economy at a sacrifice of efficiency to space them on alternate frames.

In the machinery spaces of steamers it is necessary to fit beams of extra strength wherever these can be worked without interfering with the arrangement of engines and boilers. These through beams compensate for the loss in transverse strength through the severance of the regular deck beams at the large machinery openings, and serve to tie the ship together and prevent panting of the sides at a part where a considerable weight is permanently carried. In large steamers the machinery arrangement often permits of two adjoining through beams being tied together by cover plates, thus forming an exceptionally strong beam of box section. Where strong beams cannot be fitted in one piece, owing to interference with the shipping of parts, they should be efficiently bracketed to the casing coamings, care being taken that the connection develops the strength of beam. When practicable the pillars in machinery spaces should be fitted on these through beams.

The Naval Constructor

The term half beam is applied to those deck beams which are severed in wake of hatch openings. Their inboard ends abut on the hatch side coaming plates, which are in consequence made thicker than the end ones, and the connection is commonly by a single angle clip (taking a specified number of rivets) if a continuous fore and aft angle is fitted at bottom of plate to support the beam ends, or the coaming plate is flanged under the beams for a like purpose. It will be thus seen that this rest will take a great deal of the shear off the rivet connection, besides adding to the strength of the girder formed by the coaming.

In wake of small deck openings the inboard beam end may be

ANGLE BEAM COLLAR

F1G. 171.

supported by a carling, or fore and after, of similar section to the beam, except where bulb tee is used with the *heel* of the carling abutting on beam end and connected to same with, preferably, double clips so as to get double shear value from the rivets.

Where heavy local weights or deck machinery are secured, the beams in wake of same should be increased in section, and special pillaring or deck girders fitted. It is like-

wise necessary to increase the strength of the beams at the ends of hatchways by adding to their sectional area — but not to their depth if avoidable.

The beams supporting bridge or shade decks fitted over houses and extending to ship's side are frequently carried thwartship in one bar, the casings being scored out and watertight collars fitted, in preference to cutting the beams and fitting bracket plates. These collars are shown by Fig. 171, and may be smithed, stamped, or cast in steel or malleable cast iron.

HOLD PILLARS.

Support is given the beams on the various decks by stanchions. Various sections are employed for this purpose, as round bar, pipe, I section and columns built of channel or plate and angle bar. For vessels carrying general cargoes, the pipe section, being circular and light, is probably the best. The I section makes a very

cheap and efficient column, as forged ends are done away with; and in vessels requiring large, clear, stowage spaces in holds, built columns should be fitted connected to strong deck girders. A very efficient type of built column is shown by Fig. 172, passed by Lloyd's Register for a span of 30 feet.

Figs. 173 to 186,

Where pipe pillars are adopted, the accompanying diagram giving types of solid heads and feet will be found useful.

It will be obvious that the hold pillars must be stronger than those in the lower 'tween decks, the sizes being gradually reduced as we approach the upper works, owing to the reduction in the

load which the successive tiers of pillars support.

As pillars are intended to take compressive stresses their relative strength with a given section is entirely in the end connections, and as the strongest of these is a fixed closely fitted flat end, this form should be adopted wherever possible. Where, however, it cannot be fitted, as on tank tops and with beams of section other than channel where no ridge bars are worked, care should be taken to fit closely the heads and heels on their supports, so that the load shall be taken on the column and not as a shearing stress on their fastenings, which should be relieved wherever possible of doing work.

In larger vessels, ridge bars of channel section are fitted under the beams to distribute the load taken by the pillars over all the beams and also to prevent the beams from *tripping*. In wake of hatchways where pillars are omitted or are fewer in number, intercostal plates are fitted between the beams and riveted to deck as compensation, thus forming a deck girder.

When hold pillars are stepped on inner bottom plating, a short piece of tee bar must first be riveted to tank top and caulked, and the heel of pillar afterwards riveted to the vertical stem of tee bar. A similar arrangement is adopted on expansion trunk tops of oil

steamers for heels of gangway stanchions.

Where grain or other cargoes liable to shift are carried occasionally, the hold pillars may be staggered, the heads taking alternate flanges of the centre line ridge bar, thus providing an intervening space in which to fit the shifting boards.

HATCHES.

It will be seen that a serious loss in transverse strength is sustained by cutting the beams and decks to form hatchways, and it has been explained under the caption beams how this loss is compensated for in the deck framing and by increasing the sectional area of the side coaming plates.

Hatchways should be no larger than the demands of the particular trade call for, and the corners of these openings, at least on the strength deck, should be round. While it is cheaper to make them square, it will be found false economy. In addition to making them round on the strength deck the corners must be re-enforced with doubling plates extending about 2 frame spaces each way and carried 18 inches or so around the corners. The coam-

ing angle bar must be welded; or a much better method is to run this bar to within nearly four feet of the corners around which

another section is fitted having a much broader flange on deck; this will permit of staggering the rivets and so allow more space for sufficient riveting at the junction of this bar with the deck beam. No bosom piece need be fitted to cover the butt of the corner piece with the straight length of coaming angle, Fig. 187.

End coaming plates should have "pitch" in preference to camber, as they are more easily made and allow of better fitting the wood hatch covers. The

height of coamings on weather deck must be from 2 feet to 2 feet 6 inches, and on other decks from 9 to 12 inches, care being taken that sufficient height is given to permit of the hatch batten-

Fig. 188.

ing cleats being fitted. At butts of coaming plates the covering strap should be fitted on the outside and the rivets countersunk on both sides.

A typical battening cleat is shown by Fig. 188. These may be either die forged or cast in steel and spaced not greater than 2 feet apart along the coaming plate, beginning about nine or ten

inches from the corners and sufficiently far down to give an easy fit for tarpaulin. The battening bar is of galvanized flat iron about $2\frac{1}{2} \times \frac{6}{3}$, and the butts of same must not be at corners, the bar being bent round these to allow of fitting the canvas snugly. The tarpaulin is then secured by elm or oak wedges.

The ledges on top of coamings are mostly made of a special rolled section as shown, although where this is not obtainable a

zee bar will answer equally well. These ledges should be mitred at the corners and of sufficient depth to house the hatch covers. In addition to the support afforded these by the ledge bar, fore and afters must be fitted, as well as bridle beams, to tie the hatchway, in number and scantling as required by the classification societies. The fore and afters are supported by rests riveted inside the end coamings and the hatch beams by socket slides on the sides. The only other mountings required on cargo hatches are a couple of lashing rings on each side fitted about four feet from the ends; these may be riveted on coaming plate or deck at discretion.

The wood covers should not exceed 24 inches in width, as otherwise they are too heavy, and are usually made of three pine deals, tie bolted with three §" diam. blind bolts. On the right hand sides of top a lifting bar of iron through-fastened with two clench bolts is fitted, one at each end, and the wood drilled out about 5 inches in diameter to form a receptacle for the hand. These covers must have properly cut-in marks to facilitate replacing them.

WEB FRAMES.

Web, or, as they are sometimes called, belt, frames are commonly formed by fitting a plate from 15" to 30" deep to the ordinary ship's frame, and riveting an angle bar on the inner edge to stiffen and add to the resistance of the web. They may be also built with double channel frames with a covering plate on face—an advantageous method where increased room or stowage capacity is desired. Still another method is to fit frames and reverse bars of similar section of angles, webbing them as far apart as possible consistent with the requirements of the riveted overlap. These various methods of constructing web frames have all the same object in view, viz.: to give the equivalent compensatory transverse strength lost by omitting hold beams where large spaces are required for the stowage of certain freights or in machinery spaces where hold beams cannot be fitted. It will be seen that these beams really perform the function of struts tending to resist the

water pressures on the ship's sides and the hold cargo; and for this reason, as well as those already given, should have no camber which it is conceivable tends to weaken them. If the hold beams then be left out, the necessary resistance may be given by increasing the section modulus of the side framing, and this is obtained by adding webbed frames at stated intervals along the sides, and by the more uniform subdivision in a vertical direction of the areas enclosed, by side stringers fitted intercostally between webs having a covering plate at their intersection, of diamond or half-diamond shape. The side stringers should stand squarely to the ship's frame, thereby insuring the maximum moment of resistance from the material used, as well as avoiding much bevelling of angle hars.

In addition to the foregoing, web frames are fitted wherever local losses in transverse strength take place, as at the sides of cargo doors and similar openings and over abrupt terminations of transverse strength, such as take place where a watertight bulkhead stops short of the strength deck. They are also necessary where exceptional local stresses of the nature indicated are applied.

KEELSONS.

The value of keelsons lies in their contribution to the longitudinal strength of the structure, and, where they are fitted in conjunction with intercostal plates having a shell connection, to the additional assistance given to the hull plating. In general practice it would seem that too much prominence is given to their strength as individual members rather than treating them as component members of the main structure, or ship itself viewed as a girder; this is seen in the deep centre line keelsons fitted on top of ordinary floors; where continuous centre vertical plates are also fitted, the necessary efficiency and strength required locally may be obtained by thickening the lower parts of the member, as shown in Fig. 135, and at the same time increasing the moment of inertia of the ship's section as a whole about the neutral axis.

Side stringers should be treated similarly, as illustrated by the adjoining sketch, the web instead of one flange of the channel being fitted against the reverse frame, permitting of a better connection thereto, at the same time distributing the resistance to fluid pressures over a greater surface and adding appreciably to the stowage capacity of the vessel.

Where the plates forming side stringers are 18 inches (or over) wide, bracket plates must be fitted underneath to support and keep them standing to their work, except where webs are 8 feet apart. These brackets should be fitted midway between the web frames.

The practice of piercing watertight bulkheads with keelsons and stringers, and fitting angle collars around them to insure watertightness, should be discouraged, as a much stronger member is obtained by cutting the keelson or stringer and connecting same by bracket plates to the bulkhead. This method, besides, gives a more reliably watertight connection.

In arranging keelsons or bottom longitudinals, these where possible should be incorporated with engine foundation girders, or if this be impracticable, an efficient scarph should be made by continuing them past one another for about three frame spaces before terminating.

In ships of full form or where the flat of floor is carried well forward, additional intermediate longitudinals must be fitted locally, about half the depth of centre girder and connecte to bottom plating to re-enforce the shell against "pounding."

Keelsons, longitudinals, or side stringers should never terminate abruptly, but wherever practicable should be ended on and bracketed to such supports as bulkheads, web frames, deep floors, etc. Care should also be taken to arrange the butts of these members clear of shell butts as well as "shifted" with one another. The rivets in the strap pieces should be developed to equal the strength of the member, and double shear value obtained in these connections wherever possible.

BULKHEADS.

The steel divisional partitions, built in ships, called "bulkheads," were primarily fitted to isolate the living and machinery spaces from the cargo holds proper, but were soon recognized as having a more important mission in subdividing the ship into watertight compartments besides adding considerably to transverse strength. So that in later years it has become a canon in ship design that a vessel's bulkheads shall be in number and arrangement sufficient to keep the ship afloat with any two compartments open to the Watertight bulkheads must always be carried to the deck above the load waterline, and in the case of the collision or foremost one, to the weather deck, as the forepeak is the most liable to damage and flooding, producing a great alteration in trim. They may be plated either vertically or horizontally, and efficiently stiffened in accordance with the requirements of the classification societies' rules, observing in arranging stiffeners that these are placed on the reverse to the caulking side. In most yards the practice is to fit watertight bulkheads continuous from tank top to deck level, but it is considered better construction to fit the steel decks continuous and the bulkheads intercostally.

As these steel partitions are connected to the ship's side by single

or double angle frames with closely spaced rivets in the sided flange, it will be seen that this line of perforations around the shell is a source of weakness. To compensate as far as possible for this, it is necessary to fit doubling plates, or "liners," where practicable, i.e., in wake of the outside strakes of shell plating. These liners may extend from frame to frame, or, as is more often done, for a sufficient distance on each side of bulkhead, to take another row of rivets, observing that these holes need only be spaced for watertight riveting on the caulking side of bulkhead.

Owing to the water pressures being greatest on the bottom, the plating is graded in thickness towards the top, and of course the section of stiffening bars is likewise reduced. The lower stiffeners require bracketing to tank top; and in detailing the riveting of these brackets, it should be borne in mind that one arm takes tensile and the other shearing stresses. Watertight spacing is required for all riveting except stiffeners and their connections.

Where web frames or deep framing is substituted for hold beams, additional horizontal stiffening must be given the bulkheads at the level at which the lower deck would ordinarily support the bulkhead, and in addition a deep centre line web fitted.

Generally it will be found convenient to arrange for the caulking side of bulkhead to be that side on which the open bevel frame shows, that is, the after side in fore-body bulkheads, and the forward side in after-body bulkheads. There are exceptions, however, to this rule which will suggest themselves in considering deep tank and peak water tests. As, of course, it is only necessary to caulk one side of the bulkhead, the stiffening bars should be arranged on the opposite side.

Where stiffening bars, especially angles, are exposed in cargo holds or between deck spaces, their sharp edges must be protected by fitting wood chafting pieces projecting about an inch and a half beyond the toe of bar and bolted to the stiffening flange.

SHELL PLATING.

The skin of the ship when constructed of steel is almost invariably arranged in fore and aft strakes "in" and "out" alternately. For the reasons given when treating on keels, the flat plate should be fitted as an "in" strake, so also should the sheerstrake except in large steamers where a doubling is required. For fitting and shoring purposes, it is an advantage to fit the bilge strake "inside," as well as strakes adjoining longitudinals.

In laying off the widths of strake on the midship section, it will facilitate interchangeability of individual plates if all strakes of the same thickness are made similar in width. It will also be found advantageous to work the bilge strake narrower than the

others where an odd size is unavoidable. In moderate sized vessels the outside strakes are usually from 40 to 46 inches wide, and the inside ones 48 to 54 inches, but in the largest ships it will be good practice to increase these widths, although by so doing increased riveting of butts will be necessary. On the other hand, when dealing with small vessels or light scantling craft narrower plates should be worked.

The widths having been arranged satisfactorily on the midship section, should now be transferred to a body plan and run in to the

Fig. 191.

eye as shown by Fig. 191, observing that in the fore body above the waterline the widths are kept parallel, which necessitates working stealers in the under-water body at the fore end. Running these plate widths parallel gives a straight, sharp appearance to the sight edges, a very important point when lining off a very full ship, as otherwise the rounding up lines developed would.

Fig. 192.

accentuate and exaggerate the bluff lines. In addition it enables us to work the narrow plates where the form is most difficult to work. In the after body different conditions exist, the most important plate line being that which ends at the oxter, so that it is only necessary to divide the space intervening between that point and the sheer strake into the number of strakes obtaining amidships. The ending of a plate-line in the oxter is advisable to obtain all the furnacing and difficult work on one plate only.

Having run the plate lines on body plan to fulfil the foregoing conditions, these may then be taken off and faired up on the model.

If it be found that one of the landings crosses the continuous angle of tank margin plate or watertight flat, the line must be stopped abruptly near the point of intersection and "jogged" across for a sufficient distance before resuming its flight.

Before any butts whatever are laid off, either for stringers or shell plating, a small diagram should be drawn giving the general scheme for the shift of butts which will enable the various structural plans to proceed simultaneously and independently. No butts on adjacent strakes should be placed nearer one another than two frame spaces, or one frame space where a strake intervenes. The ideal shift of butts, however, is that which shall have not more than one shell butt in any one frame space from keel to gunwale. After the shell plate butts have been arranged, those of stringers, longitudinals, keelsons, etc., may be set off in the best positions in relation to shell. Such plates as require furnacing should be arranged as short as possible, the most difficult of these being the "hip" plate on the quarters, oxter plate, boss plate, the "breeches" plate taking stern frame and plate keel, and the similar plate of spoon form forward adjoining the stem. In some forms of vessels it is also advisable to make a short plate of those having double set at fore and after ends of bilge where the latter begins to curve into the entrance and run of vessel respectively.

A scheme of butts such as the one suggested is shown by the

accompanying diagram, Fig. 192.

The "landings," as the edge overlaps of the in and out strakes of plating are called, should be of the width necessary to take the required size of rivets, which must be spaced for watertight work, i.e., 4 to 4½ diameters apart, observing that where double riveting is employed a single rivet only should be inserted at the closing, or caulking edge, in wake of all frames. In yacht construction where a perfectly smooth topside is desired, the plating is often arranged edge-butt fashion with an inside continuous seam-strap—a more expensive and less efficient method than the other, and adopted solely for appearance.

In small moderate sized vessels the garboard and sheerstrake

landings only are double riveted, but in large vessels all of the landings should be provided with two rows; and where exceptional local loads are carried, as in deep tanks, or in vessels above 480 feet in length, "the landing edges should be treble riveted for one fourth of the vessel's length in the fore and after bodies for a depth of one third the vessel's depth." Vessels slightly under this dimension may have double riveted landings with an additional rivet added in each frame space within the zone mentioned. Where a change is made from a treble to a double, or from double to single riveted landings, the taper must of course be made on the inside or hidden edge, and should extend over a frame space.

Individual plates of strakes should be fitted in as long lengths as the steel makers' limits allow, or the facilities of the particular yard permit, consistent always with good practice. The old method of fitting these with edge-butts having an inside covering strap has been almost entirely superseded by overlapping the plates, a stronger and more enduring method. There are some strakes and special cases, however, where it is still advisable to retain the edge-butt connection, as in flat plate keels, sheerstrakes and the strake in wake of bilge keels, as by this means we get a closer fitting for keel angles, stringer bars and mouldings and bilge bars, eliminating unsightly work, trouble and the expense of fitting liners.

Where the overlapped landing of an outside strake crosses the buttlap of the adjacent inside strake, it will readily be seen that a small wedge-shaped space is formed. To close this up and so obtain the necessary watertightness, it is customary to scarph the corner of the overlap, allowing it to be drawn home. In wake of the outside strake overlaps, where they adjoin the inside landing edge, planing is impracticable, and, as a similar wedge-shaped aperture interferes here also with watertightness, this is secured by fitting a tapered liner long enough to take three rivets. A similar tapering away of the outside landing edge is performed where the strakes end on stem and stern post, thus giving the appearance of one flush thickness at these parts.

Wherever the shell plating is cut to form cargo doors, coal chutes, sea connections, sidelights, etc., compensation must be given for the loss in strength sustained. More especially is this imperative where these openings occur amidships through the sheerstrake, as it is then obvious that the strength is reduced to a maximum, being at the extreme fibres and where the greatest bending moments are produced. To avoid abrupt discontinuities as much as possible, the corners of all such holes where not circular should have a bold radius, and in addition kept well clear of butts. In addition, doubling plates must be fitted, observing that these should be over the openings and encircling the upper stresses acting on the upper corners, as the stresses acting on the upper

works which need resisting most are tensile. Where sidelights are cut through the sheerstrake, compensation may be given by slightly increasing this strake in thickness or by fitting compensat-

ing angle-bars over the openings.

The shell plating, as will be seen, really forms, in conjunction with the strength deck, the sides and bottom and top members respectively of the ship viewed as a box girder. For this reason the parts taking the greatest stresses are those at the greatest distance from the neutral axis; and as a ship is not always in the upright position in a seaway, it will be evident that these parts are the sheerstrake, bottom and bilges. Thus the classification societies stipulate for thicker plating at these parts. As the greatest bending moments are exerted amidships, diminishing towards the ends, they require that the maximum thickness shall be retained for a quarter of the vessel's length before and abaft the dead flat frame. There are, however, certain localities beyond these limits where the midship thickness must be maintained if not increased where abnormal local conditions demand it. Conditions such as are referred to exist at the ends of plates adjoining the stern frame. where, besides making the connection to a heavy forging requiring very large rivets, excessive vibration of a fatiguing nature is encountered; and at the bossed plating, oxter and hip plates requiring furnacing and much consequent hammering, where a serious reduction in the original thickness takes place in addition to the distress to the plate consequent on the treatment to which it is subjected. Also doubling or increased thickness must be provided at abrupt breaks in the longitudinal strength, as at ends of poops or bridge deck superstructures, in wake of hawse pipes, etc., and at other points which present themselves and will be evident to the observant.

DETAILS. FITTINGS.

Only next in importance to the structural details are the deck and other fittings, on which the convenient and safe handling of the ship depends. These in many cases do not receive that consideration which their importance merits. Instead of being calculated on a rational basis and designed accordingly, ship fittings are too often left to the guesswork of the technically untrained, with the result that we often find in these fittings a wide variation in the scantlings employed for a given duty even amongst like fittings on the same ship where different sizes are used.

With the object, then, of proportioning these fittings from a rational unit and standardizing them, the following tables of fitting details have been prepared or collected. The basis on which the unit is founded is in many cases given, enabling the expe-

rienced to determine for themselves what variation may safely be made where fittings are being designed for special work.

In the preparation of details it will be found to contribute much to their elucidation if a "fitting list" or "bill of material" be added alongside the detail delineated, and each and every part of the fitting given a special "piece number." The number plan of the general arrangement on which the details are assembled should likewise be given, and of course these piece numbers indicated on this assembly drawing for identification. The piece numbers will also prove helpful as reference numbers in discussions or correspondence relating to the particular fitting.

The adjoining specimen plate, with its accompanying bill of material, has been prepared to illustrate the method advocated.

How to Use the Table. — At 4" thickness of plank by 5" wide, 24" spacing of frames, number of bolts will be $\frac{867}{5}$ = 173 bolts.

ANCHOR CRANE STRESSES.

In figuring the stresses on an anchor crane it is assumed that the post acts as a cantilever, the maximum stress on which occurs at the upper deck bearing. The jib is always exposed to a direct compression, while the tierods are subjected to tension.

If arrangement of blocks as shown, then

$$Q_1 = \frac{Q}{4}$$
.

In calculating the dimensions of the crane post the load on the hoisting rope = Q_1 applied at the foot block, usually fitted to a wrought iron ring around the post, has to be taken into account. Note that this block should be placed as low as possible to reduce the stresses on the post.

The shearing stresses at A: The shearing stresses at B:

$$P_1 = \frac{Q \times f + Q_1 \times b}{a} \cdot \qquad \qquad P_2 = \frac{Q \times f + Q_1(a+b)}{a} \cdot$$

Now that the forces in all the points A, B, C, D and E are known the bending moment in way of each one has to be figured out.

As for T and C, bending stresses will be produced only from the horizontal components $T_1 = T \times \cos \alpha$ and $C_1 = C \times$

cos β , while of the vertical components T_2 and C_2 equal to $T \times \sin \alpha$ and $C \times \cos \beta$ respectively. T_2 will subject the post to tension on the part DE, while $C_2 - T_2$ will act as a compressive load between A and D. As the forces keep the crane in equilibrium, it will be seen that:

$$P_1 + Q_1 + T_1$$
 must equal $P_2 + C_1$.

Bending moment at A, $M_a = 0$.

Bending moment at B, $M_b = P_1 \times a$.

Bending moment at C, $M_c = P_1 = P_1(a+b) - P_2 \times b$.

Bending moment at
$$D$$
, $M_d = P_1 (a + b + c) - P_2 (b + c) + Q_1 \times C$, or also $M_d = T_1 \times d$.

Diagram of Bending Moments.—Along the vertical lines at B, C and D set off at any scale the bending moments as found above, and join the points as shown on sketch. From this diagram the moment Mx at any intermediate point may be scaled.

Graphic Method to Determine T and S. — The stresses on the different members of the crane may be conveniently found

Frg. 218.

by graphic construction, and in most cases the result thus obtained is sufficiently accurate for practical purposes.

Take at any scale the vertical line ab to represent the load Q_1 draw bc parallel to the direction of the hoisting rope and equal to Q_1 . The dotted line will therefore represent their resultant, and drawing ad and cd parallel respectively to DF and EF, these lines will represent the stresses on jib

and tierods. From d and c draw horizontally the lines de and cf, and from d vertically the line df. Then we get $de = T_1 = T \times \cos \alpha$,

and $cf = C_1 = C \times \cos a$. Further $ae = T_2 = T \times \sin a$ and $df = C_2 = C \times \sin a$, the difference between these equal to fg representing the compression on the lower part of the post.

For getting out the shearing stress P_1 draw on a sketch of the crane a vertical line through F meeting the horizontal line from

scale equal to Q. Then HK will represent the shearing at A produced by Q_1 . Draw AL horizontally and equal to BC and make AM equal to Q_1 . If then from M a line is drawn parallel to BL the total shearing stress at A will be represented by HK + AN.

Calculation of Strength.—In figuring the dimensions of the different members in the anchor crane it is advisable not to use a factor of safety less than 6, which for ordinary wrought steel means a stress of material

= 10,000 pounds per square inch, especially if the weight of the crane itself is omitted in the calculation. Based upon a factor of safety = 6, the following formulæ are derived:—

For the *tierods*, $d = 0.08 \sqrt{T}$ where d = diameter in inches and T = tension on tierods, two of which are supposed to be fitted. For the jib, if solid circular section is being used,

 $d = 0.026 \sqrt[4]{Cl^2}$ where d = diameter in inches,

C =compression on jib and l =length of jib.

For the cranepost, if solid circular section is being used,

 $d = 0.1 \sqrt[3]{M}$ where d = diameter in inches,

and

M =bending moment in inch-pounds.

In this latter formula the stress of material is assumed equal to 9500 pounds as against 10,000 pounds in the former ones to compensate for the stress produced by the compressive load $(C_2 - T_2)$ which is not included in the calculation.

FORMULAS FOR LAYING OUT BEVEL AND MITRE GEAR BLANKS.

Frg. 220.

Formulas for Bevel Gears.

Y =No. of teeth in pinion.

$$\operatorname{Tan} S = \frac{Y}{Y'} = \frac{D}{D'}.$$

$$B = D + (0.636 P \cos S).$$

$$B = D + (0.636 P \cos S).$$
 Tan $E = \frac{0.318 P}{H} = \frac{K}{H} = \frac{2 \cos S'}{Y}.$

Tan
$$R = \frac{0.368 P}{H} = \frac{L}{H} = \frac{2.314 \cos S'}{Y}$$
.

$$O=S+E.$$

$$A = S - R.$$

$$M = \frac{D'}{2} - (0.318 P \sin S).$$

$$N = M - F \cos O.$$

$$P = \text{circular pitch.}$$

$$Y' = \text{no. of teeth in gear.}$$

$$D' = \frac{Y'P}{\pi} = 0.318 \ Y'P; \quad S' = 90^{\circ} - S.$$

$$B' = D' + (0.636 P \cos S').$$

$$N'=M'-F\cos O'.$$

$$H = \frac{D}{2\cos S'}$$

$$K = 0.318 \, P; \quad L = 0.368 \, P.$$

$$O' = S' + E; \quad A = S - R.$$
 When to be cast $K = 0.3 \, P$.
$$L = 0.4 \, P.$$

$$M' = \frac{D}{2} - (0.318 \, P \sin S').$$

Formulas for Mitre Gears.

$$P = \text{circular pitch.}$$
 $N = \text{number of teeth.}$
 $D = 0.318 \, NP = \frac{NP}{\pi}$.

 $B = D + (0.636 \, P \sin 45^\circ) = D + 0.449 \, P$.

 $A = 45^\circ - S$.

 $Tan \, S = \frac{L}{H} = \frac{0.368 \, P}{D \times 0.707}$.

 $E = 45^\circ + C$.

 $Tan \, C = \frac{K}{H} = \frac{0.318 \, P}{D \times 0.707}$.

 $M = \frac{D}{2} - (\sin 45^\circ \times 0.318 \, P) = \frac{D}{2} - 0.224 \, P$.

 $O = M - (F \cos E)$.

 $H = D \times 0.707$.

 $L = 0.368 \, P$; $K = 0.318 \, P$ (when cast

L = 0.4 P; K = 0.3 P).

NAVAL ANCHOR CRANE.

FIBRE STRESSES.

Crane Post at Forecastle Deck. -

Bending moment Wl = 3,260,000 in.-lbs.

Diameter $D = 16\frac{1}{2}$ ins.

Fibre stress = f.

Moment of resistance =
$$f \frac{\frac{\pi}{64} D^4}{\frac{D}{2}} = f \frac{\pi}{32} D^3$$
,

$$Wl = f \frac{\pi}{32} D^3.$$

$$f = \frac{Wl\ 32}{\pi D^3} = \frac{3,260,000 \times 32}{\pi \times 16.5^3} = 7390$$
 lbs. per sq. in.

At A:

$$Wl = 2,405,000 \text{ in.-lbs.}, D = 16\frac{1}{2} \text{ ins.}$$

$$f = \frac{Wl \cdot 32}{\pi D^3} = \frac{2,405,000 \times 32}{\pi \times 16.5^3} = 5460$$
 lbs. per sq. in.

At B:

$$Wl = 1,577,000 \text{ in.-lbs.}, D = 13.25 \text{ ins.}$$

$$f = \frac{Wl\ 32}{\pi D^3} = \frac{1,577,000 \times 32}{\pi \times 13.25^3} = 6910$$
 lbs. per sq. in.

At C:

$$Wl = 1,150,000 \text{ in.-lbs.}, D = 11.6 \text{ ins.}$$

$$f = \frac{Wl \, 32}{\pi D^3} = \frac{1,150,000 \times 32}{\pi \times 11.6^3} = 7500 \text{ lbs. per sq. in.}$$

At D:

$$Wl = 725,000 \text{ in.-lbs.}, D = 9.95 \text{ ins.}$$

$$f = \frac{Wl\ 32}{\pi D^3} = \frac{725,000 \times 32}{\pi \times 9.95^3} = 7500$$
 lbs. per sq. in.

At E:

$$W = 300,000 \text{ in.-lbs.}, D = 8.25 \text{ ins.}$$

$$f = \frac{Wl\ 32}{D^3} = \frac{300,000 \times 32}{\pi \times 8.25^3} = 5450$$
 lbs. per sq. in.

J1b. — Total compression on jib — P = 80,000 lbs. ± 3500 lbs. = 83,500 lbs. 8-inch extra strong pipe, outside diameter D = 8.625 ins., inside diameter d = 7.625 ins.

Modulus of elasticity E = 25,000,000.

Moment of inertia
$$I = \frac{\pi}{64} (D^4 - d^4) = \frac{\pi}{64} (8.625^4 - 7.625)^4 = 106.$$

Length l = 189 ins.

Coefficient of safety = n.

$$P = \frac{\pi^2}{n} \cdot \frac{EI}{l^2}; \quad n = \frac{\pi^2 E \cdot I}{P \cdot l^2} = \frac{2 \times 25,000,000 \times 106}{83,500 \times 188^2} = 9.$$

DIAGRAM OF STRESSES AND BENDING MOMENTS ON ANCHOR CRANE.

Area of section = 12.7 sq. ins.

Fibre stress = $\frac{83,500}{12.7}$ = 6580 lbs. per sq. in.

The Rods. — Diameter = $2\frac{1}{8}$ ins., tension on one tie rod = 24,250 ins.

Fibre stress =
$$\frac{24,250}{2.125^2 \times \pi}$$
 = 6830 lbs.

Spreader. - Section at hub of spreader.

Moment of inertia for axis $x - x = I_x = 2267$,

$$\frac{I_x}{C_x} = \frac{2267}{9} = 252.$$

Bending moment for axis x - x = 507,000 in.-lbs.

Fibre stress $f_x = \frac{507,000}{252} = 2010$ lbs. per sq. in.

Moment of inertia for axis $y - y = I_y = 186$,

$$\frac{I_{y}}{C_{y}} = \frac{186}{4.5} = 41.3.$$

Bending moment for axis y - y = 200,000 in.-lbs.

Fibre stress $f_y = \frac{200,000}{41.3}$

= 4830 lbs. per sq. in.

F1G. 222

Area of section = 49.5 sq. ins.

Compression, 18,800 lbs.

Fibre stress
$$f_c = \frac{18,800}{49.5} = 380$$
 lbs. per sq. in.

Total fibre stress

$$f_x + f_y + f_k = 2010 + 4830 + 380 = 7220$$
 lbs. per sq. in.

Section 18 ins. from hub.

$$\frac{I_x}{C_x} = \frac{701}{6.25} = 112.$$

Bending moment for axis x - x = 267,000 in.-lbs.

Fibre stress
$$f_x = \frac{267,000}{112} = 2380$$
 lbs. per sq. in.,

$$\frac{I_y}{C_y} = \frac{71.3}{3.25} = 21.9.$$

Bending moment for axis y-y=91,000 in.-lbs.

Fibre stress
$$f_y = \frac{91,000}{21.9} = 4150 \, \text{lbs. per sq. in.}$$

Area of section 33.8 sq. ins.

Compression, 18,800 lbs.

Fibre stress
$$f_c = \frac{18,800}{33.8} = 560$$
 lbs. per sq. in.

Total fibre stress =
$$f_x + f_y + f_c = 2390 + 4150 + 560$$

= 7100 lbs. per sq. in.

Tie Rod Heel Pin. — Pin considered as beam uniformly loaded and fixed at ends.

$$\frac{Pl}{8} = f \, \frac{\pi}{32} \, D^3.$$

Tension on one tie rod P = 24,250 lbs.

$$\begin{split} f &= \frac{Pl\ 32}{8\ \pi D^3} = \frac{24,250\times 5.5\times 32}{8\times \pi \times 2.875^3} \\ &= 7150\ \text{lbs. per sq. in.} \end{split}$$

Tie Rod Eye Pin. — Figured as tie rod hub pin.

$$\frac{Pl}{8} = f \frac{\pi}{32} D^3,$$

$$f = \frac{Pl 32}{8 \pi D^3} = \frac{45,800 \times 7.5 \times 32}{8 \times \pi \times 4^3}$$
= 7240 lbs. per sq. in.

NOTES ON ANCHOR CRANES.

The most suitable radius of crane to efficiently fish the anchor having been determined, this dimension in feet multiplied by the weight of anchor including stock, will give the moment in footcwts., to which reference must be made for the corresponding sizes of parts.

N.B. — These cranes are in accordance with Lloyd's requirements per Table 12, but for convenience the *moment* is given, which will be found much easier of application, and the table has

been extended to deal with the heaviest anchors.

Of course where the ship is not classed to Lloyd's, the crane should be figured out with a factor of safety of eight, when it will be found that the sizes in this table, being empirical, may be considerably reduced.

The heavier sizes of cranes may with economy be built up with structural sections, or the post and jib may be formed with angle

sections having lattice bracing.

It will also be found more economical to step the crane post or anchor deck in preference to housing it and making it revolve with the jib.

$$d = \sqrt[8]{\frac{6650 \times 32}{\pi \times 10,000}} = 1.9$$
", make 2" to allow for keyways, etc.

SHIP'S BOLLARDS (STANDARD).

Bollards are invariably made of cast iron of good quality, and should be fairly smooth castings. In small yacht and high class work they are sometimes made of gunmetal, and in battleships of steel. The bolt holes should not be cored but drilled and countersunk afterwards, the bolts being of BB iron or steel with full countersunk heads.

The diameter B of the barrel should be in accordance with the sizes given in the table, opposite the corresponding length of vessel, and with this dimension as a unit the proportionate sizes of the various parts calculated from the appended proportion table and diagram:

Diameter of bollard	•				B=1.
Centres					C = 2.83
Height					H = 1.77
Length					
Width of base					
Ends					
Diameter of top .					
Depth of ridge .					
Thickness of base					
Thickness of side					
Moulding at top.					M = .16

The Naval Constructor

BOAT HANDLING ARRANGEMENT.

The laws of the principal maritime nations require that not only shall a stated number and kind of boats, lifeboat and working, be installed on board ship, varying of course with the particular requirements of the vessel itself and the trade in which it is employed, but also that these boats shall be efficiently installed on board ship and conveniently arranged with proper boat handling appliances.* To comply with these enactments various arrangements are adopted suited to the special conditions which obtain in the particular vessel, ranging from the simple single davit handling a 10-foot dinghy slung on a single span, usual in harbor tugs and similar craft, to the row of lifeboats on a modern liner handled by steam or electric hoisters, while on the larger war vessels nests of boats are stowed and operated by special electric driven boat cranes or large derrick booms.

Before an arrangement of boat handling appliances can be laid out the special requirements governing the particular case as to number and type of boats must be considered and also the kind of davit decided upon. As already stated the rules and regulations of the hailing country and the trade will determine the former. The kind of davit suitable if the vessel be in the ocean passenger trade is restricted to two or three varieties as shown by the arrangements in the figures, these consisting of the ordinary rotating davit, the Mallory type or the Welin quadrant davit, the latter being an excellent davit but of course slightly more costly than the others, the cheapest and most convenient where there is room to install being that known as the Mallory davit.

Rotating Davits. — This is the most common type of davit used on shipboard. The davit and method of installing are shown by Fig. 242, but, of course the heelstep and bearing are susceptible of many variations to suit individual cases or local conditions. The required diameter suitable for a given weight of boat may be calculated by the equation $W \times a = \frac{\pi}{32} D^2 f$; by transpos-

$$D = \sqrt[8]{\frac{\left(\frac{Wa}{f}\right)}{\frac{\pi}{f}}},$$

ing we get diameter.

^{*} For these requirements see "Inspectors of Steam Vessels, U. S.," "Board of Trade Rules and Regulations."

ROTATING DAVIT.

the lever a, or outreach of davit, being measured with the ship inclined 10 degrees. Where the ship is intended for Lloyd's classification the formula used as required by their Rules is practically similar to the foregoing, but is differently expressed to make it more convenient of application where actual weights of boats are not at hand and to ensure uniformity of requirements. Lloyd's formula is:

$$d = \sqrt[3]{\frac{L \times B \times D (H + 4S)}{C}},$$

where L, B and D are the length, breadth and depth respectively of the boat, H is the height of the davit above its uppermost point of support, and S is the spread of the davit; each of these dimensions being in feet.

The value of the constant term C is to be as follows:—

1. When the davit is to be of wrought iron and of sufficient strength to carry the boat, its equipment and a sufficient number of men to launch it, the value of C is to be 144.

2. When the davit referred to in (1) is to be of wrought ingot steel of from 28 to 32 tons per square inch tensile strength, the value of C is to be 174.

3. When the davit is to be of wrought iron and of sufficient strength to safely lower the boat fully equipped and carrying the maximum number of persons for which it is intended, the value of C is to be 82.

4. When the davit referred to in (3) is to be of wrought ingot steel of from 28 to 32 tons per square inch tensile strength, the

value of C is to be 99.

The mountings on these davits comprise belay cleat, fairlead sheave, spectacles for span and guys, the span being clipped with sister hooks at one end and shackle on the other, and the guys shackled to spectacle and set up on deck with either lanyard or turnbuckle. On lifeboat davits, it is also obligatory to secure to davit head, lifelines of say 2-inch manila, long enough to reach to waterline and also a rope ladder from span. Where the davits operate the emergency boat (slung outboard at sea), a pudding boom should be lashed to davits suitably padded in wake of chafe to which the boat gripes are secured.

Suitable tackling for falls are readily determined from the

weight of boat.*

In first class practice the cast-steel bearing is bushed with composition either gun metal or babbit and a conical disc of hard steel is inserted in the heelstep, these additions reducing the friction with a consequent acquisition to the ease of operation.

^{*} For tackles see Knight's "Seamanship" or "The Naval Constructor."

MALLORY DAVIT.

Frg. 243.

In the larger classes of war vessels, as battleships and cruisers, a variation of this davit is adopted having a pivoting bearing and a hinged clamp at heelstep to permit of turning down the davits when clearing the deck for action. The details of this type are various, observing that the bearing is cast in steel and bronze bushed, the swivel pin of wrot steel, and the step bearing of cast steel. A forged operating lever about four feet long is furnished for turning down the davit.

Mallory Davits. — These davits are not as common in practice as their many advantages would seem to warrant. They are not proprietory as the name might imply, the designating title being derived from the line of vessels in which they are most often fitted. A reference to Fig. 243 will show that they may be formed very simply from ordinary rectangular universal roll steel of a section at bearing step derived from the equation $W \times a = \frac{bh^2}{6} f$, as in the case of the swan-neck davits described on this page, the head and heel dimension being approximately two-thirds of the resulting b and h. Where boats are stowed overhead on skid beams adjoining deck houses Mallory davits are adaptable, take up very little room, and cost much less to install than the more common rotating davit, in addition to which they are much more quickly and conveniently operated. It will be seen that they hinge on a heel pin and move outboard between guides one of which may also be utilized as the skid beams and a positive stop inserted between them to limit the outboard range of the davit.

davits are operated by tackles, the maximum pull on which will be $\frac{W}{2}a$, and the load on the handling part will equal this pull

divided by the number of parts in the purchase.

The boat, of course, is handled by the usual falls, but the

Swan-neck Davits. — These davits, illustrated by Fig. 244, are mostly adopted for torpedo boat destroyers and similar craft on account of their lightness and their adaptability to the restricted deck area associated with this class of vessel as well as on account of their speed and ease of operation. It will be noted that the boat when stowed in these davits is entirely within the ship's deck line and that no actual deck space is occupied as the boat is carried overhead and securely griped to the davits and no part of the handling gear obtrudes itself beyond the side of ship. A reference to the figure will show that a comparatively small overhang is necessary to lower the boat overboard.

SWAN-NECK DAVIT.

Davits of this type are usually made from universal roll rectangular steel bar although where extreme lightness is essential

they may be worked from structural I section.

We shall assume, then, that the davits required are intended to handle a 23-foot whaleboat commonly carried on torpedo boat destroyers, and that the weight of boat plus two men is 1300 pounds + 300 pounds equal to a total load of 1600 pounds or 800 pounds per davit. It is sometimes erroneously assumed that one davit may be subjected to the entire load and the fibre stress increased to 15,000 pounds accordingly which of course is just the same as the more correct assumption of dividing the load between the davits and assuming a fibre stress of 7500 per square inch as we have done in the calculation.

To determine the section of the davit we have to take the bending moment at A, where the greatest stress comes, with the ship, say 15 degrees, heeled over. Let us assume $b=2\frac{1}{4}$ inches. To find h we have

$$W \times a = P \times c = f \frac{bh^2}{6},$$

where

$$W = \frac{1600}{2} = 800$$
 pounds,

a = 66 inches,

c = 27 inches,

 $b = 2\frac{1}{4}$ inches.

In this case we will set the fibre stress at a low figure, 227 7500 pounds per square inch, allowing a high factor of 321cty.

MINE DAVIT.

Then:

$$\frac{1600}{2} \times 66 = 7500 \, \frac{2.25 \, h^2}{6},$$

and

$$h = \sqrt{\frac{800 \times 66 \times 6}{7500 \times 2.25}} = 4.33 \sim 4\frac{3}{8}$$
 inches.

For P we have:

$$W \times a = P \times c$$
, or $800 \times 66 = P \times 27$,

where

$$P = \frac{800 \times 66}{27} = 1956$$
 pounds.

To determine the diameter at bottom of operating screw threads it would seem reasonable to derive this from the pull P with a fibre stress of 7500 pounds per square inch, or,

$$P=f\frac{\pi d^2}{4},$$

where

P = 1956 pounds, f = 7500 pounds.

where

$$\frac{d^2}{4} = \frac{1950}{7500} = 0.26,$$

and

$$d = 0.58$$
 inch.

This, however, ignores the possibility of the screw being subjected to a bending stress or a combination of bending and compressive stresses caused by the movement of the vessel swaying the load. As the intensity of these is problematical we can only take care of it by using good judgment in selecting a suitable diameter. In the present case 1½-inch diameter over the threads should provide an ample margin.

The thrust R on pin at R is more easily determined graphically as indicated in Fig. 1. In our case we get

$$R = 3786$$
 pounds.

The section of the davit should be gradually tapered down from A towards B and C. It is good practice to make the section near head C about two-thirds of the section at A. For larger davits it is desirable to figure the strength at different sections along the davit in order to make it as light as possible.

Pins at A, B, and D should always be figured for bending to

insure proper strength. In many cases, especially in smaller davits of this kind as illustrated here, it will be found that the diameter of pin thus figured is too small to be practicable and

should, therefore, be increased properly.

Besides the athwartship screw-arm stay, an additional fore and aft stay is fitted to each davit to steady it and also to provide support against collapsing through the minor axis (especially for davits of rectangular section); this latter eventuality, however, is not likely to occur with davits of such small sizes as generally fabricated in this type.

Where occasion suggests it, it may be well to check for com-

pression by Euler's formula:

$$P = \frac{2}{4} \frac{EI}{l^2},$$

where

P = W =load in pounds,

E = modulus of elasticity,

I =moment of inertia of section,

l = vertical (projected on the load line) length of davit in inches.

f should in every case provide a sufficiently large factor of safety. As the illustration shows, the davits are tied longitudinally by wire rope span and stay to the deck, a turnbuckle being fitted to set up.

Screw Gear. — With $d=1\frac{1}{2}$ inches. For square threads the following proportions are generally adopted: —

$$h \equiv \frac{d}{4}$$
, say in this case

$$h = \frac{5''}{16}; \quad t \equiv \frac{h}{2}, \quad \sin \frac{5''}{32}.$$

Fig. 247.

To find the power P necessary to turn the hand-wheel, we have:

$$P\times r=Q\times \frac{d^1}{2},$$

where

r = radius of handwheel,

in this case = 7",
$$d^1 = 1\frac{11''}{32} = 1.34375''$$
.

WELIN DAVIT.

Fig. 248.

To find Q we have:

$$Q = W \frac{h + 2\pi \frac{d^{1}}{2} \mu}{2\pi \frac{d^{1}}{2} - h\mu},$$

where

$$W = 1956$$
 pounds (see above),
 $h = \frac{5}{16}$ -inch = 0.3125,
 $\frac{d^1}{2} = 0.671875$ inch,
 $\mu = \text{friction} - \text{coefficient}$,

in this case = abt. 0.1.

Then:

$$Q = 1956 \frac{0.3125 + 6.28 \times 0.672 \times 0.1}{6.28 \times 0.672 - 0.3125 \times 0.1} = 343 \text{ pounds}$$

and

$$P = \frac{Q \times \frac{d^1}{2}}{r} = \frac{343 \times 0.672}{7} = 33 \text{ pounds.}$$

As handwheels usually are operated by both hands each hand would exert

$$\frac{33}{2} = 16\frac{1}{2} \text{ pounds.}$$

Mountings. — The mountings or fittings on these davits comprise the span and stays previously mentioned of $1\frac{1}{2}$ -inch circ. galvanized steel or iron wire rope with turnbuckle and eyebolts through the neutral axis of davit section for securing, and lashing pad eyes, say $1\frac{7}{6}$ -inch wire by $1\frac{1}{4}$ -inch to take setting up lanyards. One pair of blocks per davit either wood or iron suited to the size of falls rove in this case 6-inch iron blocks with phosphor bronze sheaves for $2\frac{1}{4}$ -inch circ. manila and a $3\frac{3}{4}$ -inch fairlead sheave of gun metal bolted through davit where shown. A combined belay pin and slip to release the sword matting gripe which is secured at top part to an eye in davit head and a chafing pad stuffed with oakum and covered with leather to protect the whaleboat.

BOARD OF TRADE RULES FOR ROUND DAVITS— SOLID AND HOLLOW.

In many cases the regulations require the davits to be of sufficient strength to safely lower the boats into the water, fully equipped and carrying the maximum number of persons for which they measure.

It will frequently happen that the same set of davits will be used for launching both open and decked lifeboats, and the diameter of the davits should be governed by the weight of the boat which imposes the greatest load on them when loaded with the maximum number of persons for which it measures.

The weights of the various types of boat should, therefore, be ascertained from time to time; and, in estimating the weight of the persons carried, an average of 1½ cwts. (140 lbs.) should be allowed for each person.

The load on the davits includes the weight of the boat, equipments as specified in General Rules 8 and 9, maximum number of persons for which the boat measures by the rule, and blocks and falls. As the blocks are frequently made of metal and fitted with metal pulleys, their weight is considerable.

A wooden boat of section A, about 28 feet long, complete with equipments and gear as mentioned above and carrying 50 persons, is taken as imposing a load of

100 cwts. on the davits, or 2 cwts. per person for which the boat measures. This may be stated as follows:—

 $\frac{W}{N} = w, \tag{1}$

where W = total load on davits in cwts.:

N =maximum number of persons for which the boat measures;

w =load on davits in cwts. per person carried.

If the davits proposed are found to be equal in diameter to the dimensions obtained by the following rule (2), no objection need be raised, provided that, (a) the relative strength along the tapered parts is fully maintained, and (b) the total weight of the boat, equipments, maximum number of persons for which

it measures, and blocks and falls does not exceed 2 cwts. pex pexson, as ascertained by rule (1).

Fig. 249.

$$\sqrt[8]{\frac{L \times B \times D (H + 4S)}{C}} = d.$$
 (2)

Where L = length of boat, in feet;

B =breadth of boat, in feet;

D = depth of boat, in feet;

H = height of davit, in feet, above upper support;

S = span of davit, in feet;

C = constant, to be taken as 86 for iron davits, and 104 for solid ingot steel davits of from 27 to 32 tons tensile strength, and for hollow welded davits of from 26 to 30 tons tensile strength:

d = diameter, in inches, of solid davit.

In dealing with hollow davits the equivalent sections may be found by the usual formula after the cube of the required diameter of solid davit has been ascertained by rule (2), as follows:—

$$d^3 = \frac{D_h^4 - D_h^4}{D_h}, (3)$$

or

$$d_h = \sqrt[3]{\left(\frac{d^3 \times m^4}{m^4 - 1}\right)}. \tag{4}$$

Where d = diameter, in inches, of solid davit;

 D_h = outside diameter, in inches, of hollow davit;

 d_h = inside diameter, in inches, of hollow davit;

 $m = \text{the ratio } \frac{D_h}{d_h}$.

Boats vary considerably in weight, small ones being relatively heavier than large ones, and weldless steel ones heavier than wooden ones, and a modification of the constant C, rule (2), will sometimes be required. This can easily be made when the maximum weight to be imposed on the davits is known and the quantity w has been found by rule (1). In the case of weldless steel boats w may be about 2.1 cwts., in which case the modification of the constant C in rule (2) will be:—

$$\frac{C \times 2}{2.1}$$
 = modified constant.

In the case of solid iron davits, the constant, modified as above, will be:—

$$\frac{86 \times 2}{2.1} = 82$$

and for steel davits

$$\frac{104 \times 2}{2.1} = 99.$$

Formula (2) applies to boats of sections A, B, or D, in which the entire cubic capacity is measured for the persons carried, the constant C being reduced or increased as w is shown to be greater or less than 2 cwts. It also applies to boats of section C when the weight of the boat, equipments, and persons allowed,

does not exceed that of an ordinary wooden boat of similar size of Section A, B, or D.

In the case of davits which are only required to be strong enough to carry the boat and equipments and a sufficient number of men to launch it, no objection need be raised if the diameter is not less than that found by formula (2), but using a constant, C, of 144 for davits of untested material.

The constants given for steel davits are on the understanding that the material is tested and found to be within the limits given.

M.S. = Minimum size of iron in ring.

M.I.D. = Maximum internal diameter of ring.

P.L. = Proof load = $18.7 \frac{d^3}{\overline{D}}$.

d = dia. of iron in ring,

D = mean dia. of ring.

Safe load = One half the proof load.

where and

THE ORDERED LENGTHS OF COUNTERSINK POINT RIVETS.

- 1. The following curves for ordering countersink point rivets are based on the U. S. Navy standard rivets and countersink. Curves should be read to the longest "ordered length."
- 2. Where more than two thicknesses are connected, add $\frac{1}{6}$ " to each extra thickness.
- 3. Length of snap point rivets use the rule: total thickness of plates + one diam. + $\frac{1}{8}$ "; except for excessive thickness, add $\frac{1}{4}$ ".
- 4. For hydraulic riveting add \{\frac{1}{8}}" to the length required for hand or machine work.
- 5. The curves for $\frac{3}{3}$ " to $\frac{5}{3}$ " rivets are computed $\frac{1}{16}$ ", and $\frac{3}{3}$ " to 1" rivets, $\frac{1}{3}$ " longer than required to theoretically fill the hole.
 - 6. The type of head has no bearing on the ordered length.

AREAS OF SEA ANCHORS.

FORMULA.—Steamers of 400 tons gross, and under, to have 25 superficial feet of drag anchor, with the addition of 1 square foot for each 25 tons gross above the 400 tons.

Specimen formula for 1,000 tons = $25 + \frac{1,000 - 49}{25} = 49$ sf.

FRICTION BRAKE FOR CRANES.

The crane brake is solely for the purpose of preventing the load from falling when there is no other sustaining force and preventing the load from falling faster than desired when lowering. Incorrect disposition of the friction of a brake in relation to the load and power makes its purpose unattainable, and an improper proportion of friction to load makes its operation doubtful and unsatisfactory, causing it to either slip or stall the motor when trying to lower. The general features of brake friction brakes are as follows: A cam in some part of the transmission mechanism is so designed that the downward pressure of the load causes an axial pull in the shaft which presses friction

Fig. 323. — Cone Brake "Naval" Boat Crane Full Load Torque = 7880 In-Lbs.

surfaces together. The outer casing or barrel is allowed to rotate with the other parts when hoisting, but prevented from rotating when lowering by ratchet and pawls or band brake. Lowering, then, is always accompanied by relative motion between the friction discs or cones and whatever friction is developed between these tends to prevent the load from lowering and must necessarily be overcome or relieved. The proper arrangement of friction brakes is obtained by dividing the friction between the power and load ends of brake, half being on the motor side and half on the load side of the cam. Examples of this type are shown in the cone brake for a gantry crane and in the Seller's type of disc friction brake supplied for naval boat cranes. The reasons for this arrangement will be developed in the following discussion.

Case I. — Two friction brakes designed with all the friction on the load side of cam as shown on accompanying sketches, Figs. 323 and 325, one taken from the automatic brake for boat crane of battleship and the other being the brake supplied by the builders of the gantry crane. This arrangement of friction is entirely erroneous, as the motor must always keep some force on the cam to prevent the friction surfaces from separating, and allowing the load to slip. Suppose AO, Fig. 324, to represent the force required to overcome the load, applied at mean radius on the cam, OB represents the axis of the shaft. If in a given design we assume that an axial pull of OC is required

Fig. 324.

to cause sufficient friction to overcome the load, GG will represent the slope of a cam which will just supply the requisite pull. OD is its normal pressure, and AD = OC is the axial component. With cam GG the friction of the brake just balances the load supported by AO. When this brake is lowering

and the motor withdraws its pressure against the cam, the load will drop until it overtakes the power side of the cam and causes a normal pressure with an axial component sufficient to again set up the frictions. This same normal pressure always tends to drive the motor downward and it will thus be seen that even when the load is being lowered the motor must exercise a force against the cam in the direction tending to lift the load. Thus, with the above cam GG and axial component OC, we find by drawing the balance diagonal AC, that in lowering at constant speed, one-half of the load is overcome by the friction of the brake, see AL, and the other half has to be overcome by an upward pressure of the motor, see OL. Suppose we represent by R the ratio of the axial pull in the shaft due to hoisting full load to the axial pull required to just balance the load. In the case above, R=1. Suppose R=2, the axial component being AE = 2 OC, we find that when lowering at constant speed the friction of the brake overcomes $AM = \frac{2}{3}$ of the load, and the motor has to supply $OM = \frac{1}{3}$ of the load in the direction tending to lift the load. Again, if R = 3, the axial component = AF = 3 OC, and the motor lowers with $\frac{1}{4}$ load supported by the motor, ON, and \{\frac{1}{2}} load supported by the friction of the brake,

AN. Thus, if R = n, the lowering will take place with $\frac{n}{n+1}$ of the load overcome by friction in the brake and $\frac{1}{n+1}$ supported.

by a raising pressure on the motor side of the cam. In a brake with all of the friction on the load side of the cam it is obviously impossible to check the tendency of the load to drop without maintaining an upward pressure on the motor side of the cam so as to keep the friction set. The main object of an automatic brake is therefore impossible to obtain with this arrangement, and the motor is run backward against the force which it has to apply on the cam in order to keep the friction surfaces operative. The best that can be done with this arrangement is to make the value of R as large as possible, by using say 8 to 10 degrees angle of cones and as small a lead of cam as the shaft will stand, thereby reducing the value $\frac{1}{n+1}$ to be supported by the motor. A magnetic clutch on the motor, or great friction of bearings is necessary to hold the cam in such an arrangement when power is cut off from motor.

Calculation of Cone Brake for Gantry Crane.

The full-load force on $25\frac{1}{3}$ -inch pitch diameter gear is 2400 pounds. The torque then is $2400 \times \frac{25\frac{1}{3}}{2} = 30,400$ inch-pounds.

Fig. 325. — Cone Brake for Gantry Crane Full Load Torque = 30,400 In-Lbs.

Taking the mean radius of the brake cones as $9\frac{1}{2}$ inches, the force of friction required at this radius is $\frac{30,400}{9.5} = 3200$ pounds. Then if we assume a coefficient of friction of 0.1 between the friction surfaces, the normal pressure required on the cones will

be 32,000 pounds. This has to be obtained by a suitable angle of cam in combination with the slope of the friction cones. Taking the mean radius of the cam as 3 inches we get $\frac{30,400}{3} = 10,133$

pounds tangential pressure.

Referring to diagram, Fig. 327, OB represents the axis of brake shaft. Laying down this cam pressure to the scale of 10,000 pounds = 1 inch we obtain OA normal to OB. If we use 12-inch pitch for the cam its slope is represented by CD, and we find from the normal OE that the axial pull will be ON, friction not considered. Allowing for 0.15 coefficient of friction on the cam we lay off FOE an angle whose tangent is 0.15 and obtain OM as the axial pull. Extend MF and intersect same by OG the required normal pressure 32,000 pounds to scale. Perpendicular

Fig. 326. -Original Disc Brake on Gantry Crane.

to this we get the slope of the cones OH, which will obtain the above normal pressure with the given axial pull. By measurement BOH is found to be $21\frac{1}{4}$ degrees. If we use a cone angle of 20 degrees and return through the construction from H-G-F-E-CD we find that the necessary axial pull will be given by a cam whose lead is $12\frac{3}{4}$ inches. The use of 12-inch lead on cam with 20-degree cones will, therefore, furnish a friction slightly in excess of that required under the conditions mentioned. Probably the friction between the cones will never reach a lower coefficient than the 0.1 assumed, but in case this should occur the first motion will produce vibration destroying the friction on the cam surface and produce additional axial pull approaching ON. The construction of point K shows that brake will operate on a coefficient of 0.08 or less when cam friction is destroyed.

The width of the cones is determined by the pressure desired. Using 50 pounds per square inch we need $\frac{32,000}{50} = 640$ square inches area and $\frac{640}{9.5 \times 2 \pi} = 10\frac{3}{4}$ inches width, say $5\frac{1}{2}$ inches width of each cone.

The oiling system is designed to pick up oil outside of cones and deposit same between cones when lowering, so that the oil must pass continually from small to large ends of both cones.

There are, as seen by the above, and by reference to Fig. 324, three quantities inter-related in brakes of the class just designed for the gantry crane. The normal pressure required on the friction surfaces, the angle of the cones, and, the lead of the cam.

With given materials the pressure per square inch can be decided upon and the diameter and breadth of cones chosen to take the total pressure which is the frictional torque needed

C M N N B F1G. 327.

divided by the mean radius of cones and by the coefficient of friction. This quantity arranged, we can assume a value for one of the other variables and determine the remaining quantity, a couple of trials being needed to obtain a suitable set of values.

If, instead of 50 pounds per square inch, we had used materials allowing 200 pounds per square inch as in Fig. 324, the brake, Fig. 327, could have been much smaller, and a design with 6-inch mean radius of cones would have 15-degree cones each 3\frac{3}{4} inches wide with a 10-inch lead on cam of 3-inch radius.

The axial pull is least affected by friction on the cam when the lead is such as to give a cam angle of about 40 degrees, and angles between 25 and 40 degrees are therefore preferable. Lubrication of the cam should

be arranged or the operator instructed to keep cam well greased. Pawls should be designed carefully, as light as possible and nearly balanced, and their friction levers should be long enough to positively operate the pawls. Wood friction pieces slip when wet and metal pieces when oily so corks are used since they have 0.30 to 0.36 coefficient of friction under varying conditions and, with relatively smaller pressure, have 3 to 6 times the life of wood for friction blocks.

Case II. — Taking the second case, where all of the friction is gathered on the motor side of the cam, we get a brake the reverse of the above arrangement in which all of the purposes are obtainable but liable to be unsatisfactory if for any reason,

such as lack of attention to lubrication, the coefficients of friction on the working surfaces should vary greatly from those expected. Let OA, Fig. 324, again represent the lifting force of the motor on the cam, GG the slope of the cam and OC the axial component required to just balance the load. If all power be turned off the motor or even if the motor pinion or couplings be removed, the lowering tendency of the load will cause the normal pressure OD whose axial component OC locks the frictions and prevents dropping. Now suppose this brake to be designed for 0.1 coefficient of friction, the friction on the cam not being considered. If for some reason this coefficient of friction should drop to 0.08 or the friction between the sliding

Fig. 328.—Sellers Type Disc Friction Brake for Boat Crane Full Load Torque = 21,900 In. Lbs.

surfaces of the cam should become apparent, this normal pressure OD will be insufficient to lock the load. We must then design for the worst conditions allowing, say, 0.15 coefficient of friction on the cam. If this brake were allowed to run dry and the coefficient of friction between the working surfaces rose to, say 0.15, and the friction between the cam surfaces was overcome by the vibration of the machinery, then the pressure of the load on the cam would cause an axial component supplying more than twice the necessary friction, and the motor to lower must exert more than its normal power, i.e., run overloaded to force the load down.

Case III. — This state of affairs can be overcome by the arrangement of brakes shown in Figs. 325 and 328, in which the friction is divided between the motor and load ends. In these

brakes the cones or discs will have the same total area as in the foregoing case, but with a marked difference in operation. Take the case when R=1, the axial component OC, Fig. 324, will cause just enough friction to balance the load when starting to lower. The motor must overcome the difference between the resistance of the friction on its side of the cam and the turning effect of the load pressure against the cam. As soon as this is overcome the pressure betweeen the cam surfaces drops to \frac{1}{2} of its hoisting value, that is, $\frac{1}{2}$ of load AL will be overcome by friction on load side and other half OL by friction on the motor side, so that in lowering this brake the motor must give downward direction, but no power is required to lower unless R exceeds 1. brake must be designed also for minimum conditions expected. say coefficient of friction = 0.1 on sliding surfaces and = 0.15on cam surfaces. It locks to an equal extent as the brake just discussed with friction entirely on the power side of cam, but instead of using full power or overload on the motor when lowering under adverse conditions, on this brake it would only require a large force to overcome the first frictional set of the brake when starting to lower and would lower thereafter with never more than one-half of the motor's normal load, as can be seen by the discussion of Fig. 324. Even if this brake were designed well on the safe side, say $R = 1\frac{1}{4}$, to provide a margin when locking the load and should double its coefficient of friction the force of 1½ normal load which would stall the motor in Case II could be easily furnished for the instant necessary in starting by a series wound motor, and the brake thereafter would lower easily with some small downward force exerted by the motor. This last arrangement with frictions divided between motor and load ends. in addition to being effectively self-locking and unapt to stall. has the further advantage of being the least complicated of all cases as can be seen by comparison of Figs. 325 and 328.

VENTILATION.

The accompanying sketch shows a complete system of ventilation designed and calculated according to results of experiments relative to deliveries of ventilation systems on board ship made by D. W. Taylor, Naval Constructor, U.S. N., at the Experimental Model Basin, Navy Yard, Washington, D. C.

The first point to be determined in laying out any system of ship ventilation is the amount of air that is required in each compartment to be ventilated, assuming that the number of cubic feet of air to be delivered per minute as marked on set terminal is the amount required at that special point for the efficient ventilation of any compartment or com-

VENTILATION SYSTEM.

Fig. 329.

partments, such as engine rooms, water closets, cabin spaces, storerooms, magazines, etc.; the fan is then placed in the most convenient location for economy in piping. The next step is the head of the main or mains which should be as straight as possible with the number of bends reduced to a minimum. Then make the standard conditions at the first outlet 5 pounds pressure, and about 2000 feet per minute velocity. "This pressure of 5 pounds per square foot is for standard conditions of air, density corresponding to a barometric height of 30 inches, a temperature of 70 degrees Fahrenheit and a relative humidity of 70 per cent. Under these standard conditions a cubic foot of air weighs 0.07465 pound. The pressure of 5 pounds is equivalent to a pressure head of 67 feet of standard density air. A velocity of 2000 feet per minute corresponds to a velocity head of 17.27 feet. The total head then against which air is delivered to the supply main is 84.27 feet."

As the branches lead off do not change the size of the main until sufficient air has been removed to reduce the velocity to a value between 1200 and 1500 feet per minute. Then contract the mains with a taper of $1\frac{1}{2}$ inches to the foot until the area is so reduced that the velocity again becomes about 2000 feet per minute. Repeat the contraction wherever necessary, but do not reduce the final diameter of the main to less than twice the

diameter of the last branch.

A 15½-inch diameter pipe is selected for the first section of the main, on account of giving the nearest velocity to 2000 feet per minute. After branches A, B, and C have been taken off the velocity is reduced to 1458 feet per minute. Being below 1500 feet per minute the main is reduced in size with a taper of 1½ inches to the foot to 13-inch diameter which increases the velocity to 2007 feet per minute. At the beginning of the 13-inch diameter or B.B. section of the main, the direction is changed 90 degrees which should be done with an elbow having a radius of throat not less than diameter of pipe. When branches D and E have been taken off the velocity becomes 1302 feet per minute; the main is again reduced in size with a taper $1\frac{1}{2}$ inches to the foot to 10½-inch diameter increasing the velocity to 1995, and again branches F and G reduce the velocity to 1247 feet per minute, which necessitates changing the size of the main to 8½-inch diameter, bringing the velocity up to 2020 feet per minute. Branches H and I again reduce it to 1212 feet per minute as the main should never be reduced to less than twice the diameter of the last branch but it can now only be reduced to about 7-inch diameter to be settled definitely later when sizes of branches are determined.

FRICTION BRAKE FOR CRANES.

The crane brake is solely for the purpose of preventing the load from falling when there is no other sustaining force and preventing the load from falling faster than desired when lowering. Incorrect disposition of the friction of a brake in relation to the load and power makes its purpose unattainable, and an improper proportion of friction to load makes its operation doubtful and unsatisfactory, causing it to either slip or stall the motor when trying to lower. The general features of brake friction brakes are as follows: A cam in some part of the transmission mechanism is so designed that the downward pressure of the load causes an axial pull in the shaft which presses friction

Fig. 323.—Cone Brake "Naval" Boat Crane Full Load Torque = 7880 In-Lbs.

surfaces together. The outer casing or barrel is allowed to rotate with the other parts when hoisting, but prevented from rotating when lowering by ratchet and pawls or band brake. Lowering, then, is always accompanied by relative motion between the friction discs or cones and whatever friction is developed between these tends to prevent the load from lowering and must necessarily be overcome or relieved. The proper arrangement of friction brakes is obtained by dividing the friction between the power and load ends of brake, half being on the motor side and half on the load side of the cam. Examples of this type are shown in the cone brake for a gantry crane and in the Seller's type of disc friction brake supplied for naval boat cranes. The reasons for this arrangement will be developed in the following discussion.

Case I. — Two friction brakes designed with all the friction on the load side of cam as shown on accompanying sketches, Figs. 323 and 325, one taken from the automatic brake for boat crane of battleship and the other being the brake supplied by the builders of the gantry crane. This arrangement of friction is entirely erroneous, as the motor must always keep some force on the cam to prevent the friction surfaces from separating, and allowing the load to slip. Suppose AO, Fig. 324, to represent the force required to overcome the load, applied at mean radius on the cam, OB represents the axis of the shaft. If in a given design we assume that an axial pull of OC is required

Fig. 324.

to cause sufficient friction to overcome the load, GG will represent the slope of a cam which will just supply the requisite pull. OD is its normal pressure, and AD = OC is the axial component. With cam GG the friction of the brake just balances the load supported by AO. When this brake is lowering

and the motor withdraws its pressure against the cam, the load will drop until it overtakes the power side of the cam and causes a normal pressure with an axial component sufficient to again set up the frictions. This same normal pressure always tends to drive the motor downward and it will thus be seen that even when the load is being lowered the motor must exercise a force against the cam in the direction tending to lift the load. Thus, with the above cam GG and axial component OC, we find by drawing the balance diagonal AC, that in lowering at constant speed, one-half of the load is overcome by the friction of the brake see AL, and the other half has to be overcome by an upward pressure of the motor, see OL. Suppose we represent by R the ratio of the axial pull in the shaft due to hoisting full load to the axial pull required to just balance the load. In the case above, R = 1. Suppose R = 2, the axial component being AE = 2 OC, we find that when lowering at constant speed the friction of the brake overcomes $AM = \frac{2}{3}$ of the load, and the motor has to supply $OM = \frac{1}{3}$ of the load in the direction tending to lift the load. Again, if R = 3, the axial component =AF=3 OC, and the motor lowers with $\frac{1}{4}$ load supported by the motor, ON, and $\frac{3}{4}$ load supported by the friction of the brake,

AN. Thus, if R = n, the lowering will take place with $\frac{n}{n+1}$ of the load overcome by friction in the brake and $\frac{1}{n+1}$ supported

by a raising pressure on the motor side of the cam. In a brake with all of the friction on the load side of the cam it is obviously impossible to check the tendency of the load to drop without maintaining an upward pressure on the motor side of the cam so as to keep the friction set. The main object of an automatic brake is therefore impossible to obtain with this arrangement, and the motor is run backward against the force which it has to apply on the cam in order to keep the friction surfaces operative. The best that can be done with this arrangement is to make the value of R as large as possible, by using say 8 to 10 degrees angle of cones and as small a lead of cam as the shaft will stand, thereby reducing the value $\frac{1}{n+1}$ to be supported by the motor. A magnetic clutch on the motor, or great friction of bearings is necessary to hold the cam in such an arrangement when power is cut off from motor.

Calculation of Cone Brake for Gantry Crane.

The full-load force on $25\frac{1}{3}$ -inch pitch diameter gear is 2400 pounds. The torque then is $2400 \times \frac{25\frac{1}{3}}{2} = 30,400$ inch-pounds.

Fig. 325. — Cone Brake for Gantry Crane Full Load Torque = 30,400 In-Lbs.

Taking the mean radius of the brake cones as $9\frac{1}{2}$ inches, the force of friction required at this radius is $\frac{30,400}{9.5} = 3200$ pounds. Then if we assume a coefficient of friction of 0.1 between the friction surfaces, the normal pressure required on the cones will

be 32,000 pounds. This has to be obtained by a suitable angle of cam in combination with the slope of the friction cones. Taking the mean radius of the cam as 3 inches we get $\frac{30,400}{3} = 10,133$

pounds tangential pressure.

Referring to diagram, Fig. 327, OB represents the axis of brake shaft. Laying down this cam pressure to the scale of 10,000 pounds = 1 inch we obtain OA normal to OB. If we use 12-inch pitch for the cam its slope is represented by CD, and we find from the normal OE that the axial pull will be ON, friction not considered. Allowing for 0.15 coefficient of friction on the cam we lay off FOE an angle whose tangent is 0.15 and obtain OM as the axial pull. Extend MF and intersect same by OG the required normal pressure 32,000 pounds to scale. Perpendicular

Fig. 326. - Original Disc Brake on Gantry Crane.

to this we get the slope of the cones OH, which will obtain the above normal pressure with the given axial pull. By measurement BOH is found to be $21\frac{1}{4}$ degrees. If we use a cone angle of 20 degrees and return through the construction from H–G–F–E–CD we find that the necessary axial pull will be given by a cam whose lead is $12\frac{3}{4}$ inches. The use of 12-inch lead on cam with 20-degree cones will, therefore, furnish a friction slightly in excess of that required under the conditions mentioned. Probably the friction between the cones will never reach a lower coefficient than the 0.1 assumed, but in case this should occur the first motion will produce vibration destroying the friction on the cam surface and produce additional axial pull approaching ON. The construction of point K shows that brake will operate on a coefficient of 0.08 or less when cam friction is destroyed.

The width of the cones is determined by the pressure desired. Using 50 pounds per square inch we need $\frac{32,000}{50} = 640$ square inches area and $\frac{640}{9.5 \times 2 \pi} = 10\frac{3}{4}$ inches width, say $5\frac{1}{2}$ inches width of each cone.

The oiling system is designed to pick up oil outside of cones and deposit same between cones when lowering, so that the oil must pass continually from small to large ends of both cones.

There are, as seen by the above, and by reference to Fig. 324, three quantities inter-related in brakes of the class just designed for the gantry crane. The normal pressure required on the friction surfaces, the angle of the cones, and, the lead of the cam.

With given materials the pressure per square inch can be decided upon and the diameter and breadth of cones chosen to take the total pressure which is the frictional torque needed

divided by the mean radius of cones and by the coefficient of friction. This quantity arranged, we can assume a value for one of the other variables and determine the remaining quantity, a couple of trials being needed to obtain a suitable set of values.

If, instead of 50 pounds per square inch, we had used materials allowing 200 pounds per square inch as in Fig. 324, the brake, Fig. 327, could have been much smaller, and a design with 6-inch mean radius of cones would have 15-degree cones each 3\frac{3}{4} inches wide with a 10-inch lead on cam of 3-inch radius.

The axial pull is least affected by friction on the cam when the lead is such as to give a cam angle of about 40 degrees, and angles between 25 and 40 degrees are therefore preferable. Lubrication of the cam should

be arranged or the operator instructed to keep cam well greased. Pawls should be designed carefully, as light as possible and nearly balanced, and their friction levers should be long enough to positively operate the pawls. Wood friction pieces slip when wet and metal pieces when oily so corks are used since they have 0.30 to 0.36 coefficient of friction under varying conditions and, with relatively smaller pressure, have 3 to 6 times the life of wood for friction blocks.

Case II. — Taking the second case, where all of the friction is gathered on the motor side of the cam, we get a brake the reverse of the above arrangement in which all of the purposes are obtainable but liable to be unsatisfactory if for any reason,

as lack of attention to lubrication, the coefficients of friction he working surfaces should vary greatly from those expected. OA, Fig. 324, again represent the lifting force of the motor he cam, GG the slope of the cam and OC the axial compote required to just balance the load. If all power be led off the motor or even if the motor pinion or couplings emoved, the lowering tendency of the load will cause the nal pressure OD whose axial component OC locks the fricand prevents dropping. Now suppose this brake to be gned for 0.1 coefficient of friction, the friction on the cam being considered. If for some reason this coefficient of ion should drop to 0.08 or the friction between the sliding

Fig. 328.—Sellers Type Disc Friction Brake for Boat Crane Full Load Torque = 21,900 In. Lbs.

aces of the cam should become apparent, this normal pres-OD will be insufficient to lock the load. We must then design the worst conditions allowing, say, 0.15 coefficient of friction he cam. If this brake were allowed to run dry and the coient of friction between the working surfaces rose to, say 0.15,

the friction between the cam surfaces was overcome by vibration of the machinery, then the pressure of the load the cam would cause an axial component supplying more 1 twice the necessary friction, and the motor to lower must t more than its normal power, *i.e.*, run overloaded to force load down.

ase III. — This state of affairs can be overcome by the ngement of brakes shown in Figs. 325 and 328, in which the ion is divided between the motor and load ends. In these

brakes the cones or discs will have the same total area as in the foregoing case, but with a marked difference in operation. Take the case when R = 1, the axial component OC, Fig. 324, will cause just enough friction to balance the load when starting to lower. The motor must overcome the difference between the resistance of the friction on its side of the cam and the turning effect of the load pressure against the cam. As soon as this is overcome the pressure betweeen the cam surfaces drops to 1 of its hoisting value, that is, \(\frac{1}{2}\) of load AL will be overcome by friction on load side and other half OL by friction on the motor side, so that in lowering this brake the motor must give downward direction, but no power is required to lower unless R exceeds 1. This brake must be designed also for minimum conditions expected, say coefficient of friction = 0.1 on sliding surfaces and = 0.15 on cam surfaces. It locks to an equal extent as the brake just discussed with friction entirely on the power side of cam, but instead of using full power or overload on the motor when lowering under adverse conditions, on this brake it would only require a large force to overcome the first frictional set of the brake when starting to lower and would lower thereafter with never more than one-half of the motor's normal load, as can be seen by the discussion of Fig. 324. Even if this brake were designed well on the safe side, say $R = 1\frac{1}{4}$, to provide a margin when locking the load and should double its coefficient of friction the force of 14 normal load which would stall the motor in Case II could be easily furnished for the instant necessary in starting by a series wound motor, and the brake thereafter would lower easily with some small downward force exerted by the motor. This last arrangement with frictions divided between motor and load ends. in addition to being effectively self-locking and unapt to stall has the further advantage of being the least complicated of all cases as can be seen by comparison of Figs. 325 and 328.

VENTILATION.

The accompanying sketch shows a complete system of ventilation designed and calculated according to results of experiments relative to deliveries of ventilation systems on board ship made by D. W. Taylor, Naval Constructor, U.S. N., at the Experimental Model Basin, Navy Yard, Washington, D. C.

The first point to be determined in laying out any system of ship ventilation is the amount of air that is required in each compartment to be ventilated, assuming that the number of cubic feet of air to be delivered per minute as marked on sketch at each terminal is the amount required at that special point for the efficient ventilation of any compartment or com-

VENTILATION SYSTEM.

Fig. 329.

partments, such as engine rooms, water closets, cabin spaces, storerooms, magazines, etc.; the fan is then placed in the most convenient location for economy in piping. The next step is the head of the main or mains which should be as straight as possible with the number of bends reduced to a minimum. Then make the standard conditions at the first outlet 5 pounds pressure, and about 2000 feet per minute velocity. "This pressure of 5 pounds per square foot is for standard conditions of air. density corresponding to a barometric height of 30 inches, a temperature of 70 degrees Fahrenheit and a relative humidity of 70 per cent. Under these standard conditions a cubic foot of air weighs 0.07465 pound. The pressure of 5 pounds is equivalent to a pressure head of 67 feet of standard density air. A velocity of 2000 feet per minute corresponds to a velocity head of 17.27 feet. The total head then against which air is delivered to the supply main is 84.27 feet."

As the branches lead off do not change the size of the main until sufficient air has been removed to reduce the velocity to a value between 1200 and 1500 feet per minute. Then contract the mains with a taper of $1\frac{1}{2}$ inches to the foot until the area is so reduced that the velocity again becomes about 2000 feet per minute. Repeat the contraction wherever necessary, but do not reduce the final diameter of the main to less than twice the

diameter of the last branch.

A 15½-inch diameter pipe is selected for the first section of the main, on account of giving the nearest velocity to 2000 feet per minute. After branches A, B, and C have been taken off the velocity is reduced to 1458 feet per minute. Being below 1500 feet per minute the main is reduced in size with a taper of $1\frac{1}{2}$ inches to the foot to 13-inch diameter which increases the velocity to 2007 feet per minute. At the beginning of the 13-inch diameter or B.B. section of the main, the direction is changed 90 degrees which should be done with an elbow having a radius of throat not less than diameter of pipe. When branches D and E have been taken off the velocity becomes 1302 feet per minute; the main is again reduced in size with a taper 1½ inches to the foot to 10½-inch diameter increasing the velocity to 1995, and again branches F and G reduce the velocity to 1247 feet per minute, which necessitates changing the size of the main to 81-inch diameter, bringing the velocity up to 2020 feet per minute. Branches H and I again reduce it to 1212 feet per minute as the main should never be reduced to less than twice the diameter of the last branch but it can now only be reduced to about 7-inch diameter to be settled definitely later when sizes of branches are determined.

The formula for velocity in ventilation pipes is

$$Area = \frac{Volume}{Velocity}.$$

Knowing everywhere the size and the lead of the main, the next point to be considered is the size of the branches which is governed largely by the distance of the point of intersection of the branch with the main from the fan. This is due to the loss in delivery

of air due to friction in the main up to this point.

The formula for loss of head in a round or square pipe is $H_F = 4 F \frac{L}{J} V_1^2$, where H_F is loss of head in feet of air due to friction, F is the coefficient of friction, L and d are length and diameter of the pipe, respectively, both expressed in feet or both in inches, and V_1 is the velocity of flow through the pipe in feet per second. If we change V_1 to V or velocity in feet per minute and

give F its proper value for first class piping, namely, 0.00008. we have upon substituting and reducing

$$H_F = \frac{L}{d} \frac{V^2}{11.250.000}$$
.

For practical purposes it is only necessary to figure the loss of head in feet of air due to friction for each section of the main, and the size of all branches leading off from that section of the main should be governed by the loss of head figured for the entire section. Such being the case we should substitute

for V in the formula for loss of head given above $\sqrt{\frac{V^2V_2^2}{2}}$, where V is the velocity in feet per minute at the beginning of any section of the main and V_2 is the velocity in feet per minute at the end of the same section. This velocity is called the

mean velocity for that section of the main. The main velocities for the different sections of the main on the accompanying sketch are as follows: --

SECTION A.A.

M.V. =
$$\sqrt{\frac{(1970)^2 + (1655)^2}{2}}$$
 = 1819.

SECTION B.B.

M.V. =
$$\sqrt{\frac{(2007)^2 + (1845)^2}{2}}$$
 = 1928.

SECTION C.C.

M.V. =
$$\sqrt{\frac{(1995)^2 + (1787)^2}{2}}$$
 = 1894.

SECTION D.D.

M.V. =
$$\sqrt{\frac{(2020)^2 + (1616)^2}{2}}$$
 = 1829.

SECTION E.E.

M.V. =
$$\sqrt{\frac{(1684) + (842)^2}{2}}$$
 = 1331.

From the experiments above mentioned it was concluded that each foot of head lost means an approximate loss of about 0.6 of one per cent of delivery as compared with standard conditions. In consideration of this fact the percentage of loss in deliveries of air due to friction for the different sections of the main on the accompanying sketch is as follows:—

Remarks.	EACH SECTION.	TOTAL FROM FAN.
SECTION A.A. Diam. = 15½", length = 183", M.V. = 1819 H _F = \frac{133\times(1819)^2}{15.25\times(1.250.000)} = 3.53\times(0.6) =	Per cent.	Per cent.
SECTION B.B. Diam.=13", length=134", M.V.=1928		
$H_F = \frac{134 \times (\bar{1}928)^2}{13 \times 11,250,000} = 3.4 \times 0.6 =$ Section C.C. Diam. = 10½", length = 88", M.V. = 1894	2.04	4.16
$H_F = \frac{88 \times (1894)^2}{10.5 \times 11,250,000} = 2.67 \times 0.6 =$ SECTION D.D.	1.6	5.76
Diam. =8\frac{1}{1}\text{, length = 101'', M.V. = 1829} $H_F = \frac{101 \times (1829)^2}{8.25 \times 11,250,000} = 3.64 \times 0.6 =$	2.18	7.94
SECTION E.E., Diam. = 7", length = 48", M.V. = 1331 $H_F = \frac{48 \times (1331)^2}{7 \times 11,250,000} = 1.08 \times 0.6 =$	0.65	8.59

For general run of branches make the angle anything less than 45 degrees; 30 degrees is a very good angle, but it is not necessary to adhere to it rigidly. For the branches at the extreme end of the main, where the velocity is very much reduced, the angle should be increased and the last branch should generally lead off at 90 degrees.

In determining the inside diameter of the branches an allowance should be added to the length of the branch along centre line for elbow, as follows:—for one 90-degree elbow add.

3 feet, for two add 7 feet, for three add 7 feet. For elbows less

than 90 degrees add in proportion. This applies to elbows whose radius to the center of the pipe is $1\frac{1}{2}$ diameters. A smaller radius should never be used. Take branch J for instance, where 225 cubic feet per minute are needed; the loss of delivery in the main up to this point is 8.59 per cent and the actual delivery to be expected will be only 0.9141 of the standard delivery; the standard delivery then would be $\frac{225}{0.9141} = 246$ cubic feet per minute. As branch J is about $17\frac{1}{2}$ feet long and has two 90-degree elbows and one 45-degree elbow, we should add about $8\frac{1}{2}$ feet to the length, which would make it 26 feet long. Now if the inside diameter of branch J is made of a size (see Fig. 330) to pass 246 cubic feet length 26 feet under standard conditions, it may be expected to give the required 225 cubic feet under actual conditions. The sizes of all branches are determined by the same method.

The length and size of branches being determined, connect these with their outlet fittings by a cone expanding 1½ inches to the foot to the desired diameter for the velocity required on the accompanying sketch. The outlet fittings are all shown adjustable elbows which are usually fitted on all supply systems on

government vessels. Any style terminal may be used.

The air is to be renewed in the various spaces approximately as follows, based on the gross capacity of the compartments. and on the above pressure:

Quarters on orlop deck, in from ten to twelve minutes. Water closets, in from four to six minutes.

Storerooms, in from eight to twelve minutes.

Magazines, in from six to eight minutes.

Engine rooms and steering compartments, in about two minutes.

Ice-machine room, in about three minutes.

Dynamo rooms, in about three-fourths of a minute.

Hemp. — Hemp rope deteriorates rapidly when exposed to wind and weather, and for this reason, when practicable, it is tarred, although doing so weakens it. Hemp should only be used for warps and bolt ropes of sails, as it is much too hard for other purposes, more especially when wet.

The following rules give the equivalent circumference of tarred and white hemp rope for a working load in tons of one third the breaking stress:—

 $\sqrt{7 \times \text{load}} = \text{circumference of white rope.}$ $\sqrt{9 \times \text{load}} = \text{circumference of tarred rope.}$

Length of Reel

Other Rope. — A variety of small stuff is used in ship work for sundry purposes, the principal kinds of which, and their purposes, follow:—

COTTON ROPE is only used for halliards and sheets in small craft,

being much softer than Manila.

Houseline is used for lacing sails, etc.

Marline is a small kind of tarred hemp, used for serving ropes and splices.

Serving twine (tarred or waxed) is used for whipping the ends of ropes and other small jobs.

CHAPTER II.

BLOCKS.

Blocks are divided broadly into two varieties, wood and iron, the former being used when reeving falls or tackles of Manila, and the latter for wire rope. Wood blocks are either "made" or "mortised," and may have metal or lignum-vitæ sheaves. The space in the block between the wood and the sheave is called the "swallow," the opposite end of the block being named the "breech," and the sides the "cheeks." The frame of the block may be strapped with iron or rope, a score being cut to form a housing for same.

All good blocks should be fitted with patent roller sheaves, especially for halliards and sheets, or for any heavy work. For topsail, sheet, throat and peak halliard purchases, etc., ash blocks, rope stopped, should be used. For derricks on freighters, where wire rope is used for heavy loads, iron blocks are best; where Manila falls and topping lifts are fitted, wood blocks are most suitable.

It will be evident that a good deal of power can be wasted by friction of the sheave on pin, and also by the rope chafing, through insufficient "swallow." To minimize the loss due to friction through the former cause, the pins should be bushed. Various bushings are employed for this purpose, probably the most efficient being a gunmetal or bronze sheave with spotted graphite hext the pin.

The loss due to friction is 10 per cent for each sheave.

Blocks are designated "single," "double," or "treble," in accordance with the number of sheaves fitted, and are variously named to denote either a particular shape or as indicating the purpose for which they are intended. Some of the more common bnes are:—

Snatch Blocks are used to divert the lead on the hauling part of a fall or tackle, having for this purpose a hinged part on one of the cheeks, to permit of placing the rope in, which would otherwise require reeving—a tedious and often impracticable process. They are usually fitted at heels of derricks, and on deck, to take varping and other leads, and are mostly made of iron, the old-asshioned wood snatch block being clumsy and cumbersome.

Fiddle Blocks take the name from their resemblance to the astrument, being constructed with two sheaves placed tandem, to ermit of reeving separate halliards leading in opposite directions.

They are to be found on peak-halliards, at preventer stay tackles, etc., and are made in wood where Manila is rove, and in iron for wire rope.

Gin Blocks are used on derrick heads and spans in conjunction with a whip for handling cargo, and comprise a skeleton frame and sheave of iron.

Cat and Fish Blocks are fitted to the anchor davit, or crane, and consist of a pair of blocks with double or treble sheaves, having a large swallow. The fish (or lower) block has a large hook, sometimes made to trip, for fishing the anchor by the gravity band on the stock. These blocks are made in both wood and iron, the latter being often fitted with Manila falls.

Clump Blocks are made short and thick, as their name implies. They are used for tacks and sheets, and for this reason are extra large in the swallow. Made in wood and iron.

Wrecking Blocks are large, extra heavy iron strapped blocks, with lashing shackles, and are used for rigging up special derricks for temporary use with heavy loads.

Cheek-Blocks have only one side, the other cheek being

formed by fitting against a spar.

The size of a block is designated by the length of the shell, and this is determined from the circumference of the rope which it reeves, as a unit. For most purposes three times the size of rope gives a suitable block, but in a few cases, where the minimum of friction and extra ease is desired in the swallow, as with blocks for boat dayit tackles, three and one half times should be taken, e.g., a block for ordinary purposes to reeve three-inch Manila would be 9 inches, but if required for davit falls, the size would be increased to 10 inches. The diameter of sheave is usually about two thirds of the size of block, a 12-inch block having an 8-inch diameter sheave.

In ordering blocks it is necessary to prepare a list, giving a concise but full and exact description of each individual block,

embracing the following points: -

Sheaves. — The number of sheaves to be indicated by "S," "D," or "T," and whether of lignum-vitæ, brass, or iron sheaves, bushed or patent roller bushed.

Name. — The purpose for which the block is intended should be given, as, "jib-sheets," "derrick falls," etc.

Shackles should be very clearly specified where they are for special fittings. Ordinarily the shackle is fitted with its pin at right angles to the axis of the sheave, this being the most natural

way to engage the strap of block, therefore when the word "shackle," without further description, is used, it is always fitted in this manner. Where, however, it is essential to have it with the shackle pin running parallel with sheave pin (as is often necessary to get the falls of a tackle to lead in line with hauling part) the words "reverse shackle" must be used. If the shackle be required with its jaw uppermost, "reverse upset shackle" should be specified.

It often happens that a block is required with an eye to engage a shackle, which the blockmaker is not required to furnish. In such cases it is well to state whether the eye should be "worked or a "shackle-eye" wanted. A "worked eye," of course, is one having its edge worked round like a ring, the "shackle-eye" being drilled straight through, so that the inserted pin bears along its entire length. For a given diameter of pin, that in a shackle-eye would be twice as strong as the one bearing on a worked eye, so that where other considerations do not count, it is economy to fit a shackle eye.

Beckets are small eyes fastened at the breech end of blocks to take the thimble on the standing part of a tackle. They are useful to have on all spare tackle blocks.

Strops. — When blocks are intended for brace or guy pendants, they should be specified as having a score cut to receive the rope strop.

Hooks should not be used on blocks where heavy loads are dealt with. For loads under ten tons they are equally reliable with shackles, besides being handier. They should be specified as "loose," "stiff front," "side," or "swivel" hook, as required, and the working load given in all cases, as many of the hooks on low grade blocks are considerably inferior in strength to the other parts of the fitting.

Sister, or Match Hooks are used for a variety of purposes, and consist of two hooks on a common eye, arranged to open, and when closed, to form a seemingly solid eye.

Lashing Shackles are especially large in the bow, and wider at the jaws, than ordinary shackles, being fitted to the heavier classes of double and treble blocks, to permit of their taking a Manila or wire rope lashing.

Swivel Jaws are sometimes fitted to the upper block in davit tackles.

Appended is a table giving actual weights of blocks, fitted with shackles and beckets complete, which will be of use in estimating rigging and outfit weights.

Guns less than 3" cals. are chambered for fixed ammunition with the powder and projectiles in brass cartridge cases. Guns from 3" cals. upwards, and including the 6" L 45 gun, can be chambered to use either fixed ammunition, or loose ammunition with the powder in cartridge bags and the projectile separate from the powder. Guns above 6" cal. and including the 6" L 45 gun are chambered for loose ammunition. The breech mechanisms of all guns up to 10" are operated by

SECTION IV.

RIGGING AND ROPES.

CHAPTER I.

The rigging and ropes of a modern steamship still constitute a very important part of the vessel's equipment, notwithstanding the almost total abolition of sail area, and its extinction as a propelling agent in the present day steamer.

propelling agent in the present day steamer.

Generally too little attention is devoted to what are considered the minor details of a steamship's rigging, by those best qualified to determine the sizes of ropes and blocks, and the arrangement of tackles on a mechanical basis. The array of derricks around the masts and kingposts of a freighter, with their varying loads of from 2½ to 50 tons, exemplify the necessity for a closer acquaintance with the staying, guying and tackling of these appliances, to ensure that the whole of the system shall be designed throughout on an uniform basis.

RIGGING.

By the term "rigging" is generally denoted the standing rigging, or that part whose function is to stay or support the masts, spars and funnels, and comprises the shrouds, guys, pendants, bowsprit shrouds, jib-boom guys, stays and backstays. These supports are now invariably made of galvanized wire rope, either iron or mild steel, the latter being employed where strength and lightness are desired, or where heavy working derricks are fitted. A special quality called plough steel, is sometimes used when exceptionally great loads have to be lifted. Indeed, it will often be found cheaper to employ plough steel in these cases, as the number of shrouds or stays may thereby be reduced, thus effecting a greater saving in the quantity required than the extra cost in quality has involved.

Wire Rope.—As its name implies, wire rope is manufactured from small steel or iron wires, twisted into strands, six of which (usually) are laid up around a tarred hemp centre, the strands having a wire heart where strength is more important than flexi-

bility, otherwise where used as running gear and flexibility is a necessity they also have a hempen centre. The number of wires constituting a strand varies with the degree of flexibility required, 19 wires to a strand being ordinary flexible rope, and 37 wires extra flexible, such as would be used for derrick topping lifts. Steel wire rope for ship rigging should always be galvanized, otherwise it deteriorates rapidly, and where it is used for running gear, it should be soaked in boiling tallow and linseed oil, a process which will add much to its life.

Great care must be used at all times in handling it so as to avoid sharp nips or kinks, either of which is fatal. For this reason when used as hawsers, wire rope must be stowed on a reel having a core of suitable diameter, and in the case of running rigging, the proper diameter of sheave for a given size of wire is important. An undersized sheave shortens the life of the best rope, and by

distorting the fibres, weakens its strength.

Approximate diameters of sheaves for extra flexible steel wire rope, are given in the table on page 381.

Splices. — Splices in wire rope, such as are necessary around thimbles and elsewhere, weaken its strength from 10 to 15 per cent. It is necessary, therefore, to take account of this in fixing on the safe working load. Likewise in ordering the lengths of rope, allowance must be made on net sizes for the number of splices worked.

Thimbles.—In working eyes in the ends of wire rope, it is necessary that the fibres forming the inside of eye should be protected from the destructive effect of a link or shackle pin bearing on same. To guard against this, the splice is worked around heart shaped eyes or thimbles. These, like the sheaves, must be of a suitable size for a given circumference of rope.

SHEAVES FOR EXTRA FLEXIBLE STEEL WIRE ROPE.

The Naval Constructor

WIRE ROPE END-FITTINGS.

Figs. 337-344.

Rope End Fittings. — Another method of forming an eye on the end of wire rope, is to work an open eye with groove-shaped ends, to enclose the rope, and through which they are riveted as shown in the plate. This "shoe," however, is rarely resorted to unless on the bowsprit shrouds, and similar rigging on yachts, where small close-fitting eyes are desired for neat appearance.

Some of the more common forms of wire rope end fittings are illustrated on the preceding page. Their various uses will suggest themselves to the observant.

Parcelling and Serving.— In ordinary merchant work, the lower ends of shrouds and stays for 6 or 7 feet are wormed and parcelled with two overlapping layers of cotton sheeting, painted and thereafter served. Where stays are subjected to much chafing, they should be doubly served and covered with leather in the collars.

No serving must be fitted on stays which carry sails, as it would only be cut to pieces by the chafe of the hanks.

Turnbuckles. — Standing rigging is invariably set up with turnbuckles, or rigging screws to enable the wire to be tautened, as quite an appreciable amount of "stretch" takes place, more particularly in new rope.

These screws are proportioned to the breaking strength of the wire, which should be *spliced* around a solid heart-shaped core for the heavier sizes, or an open thimble in the case of light wire. Where used for shrouds, the lower end must be arranged to swivel freely, and the pad-eye riveted to sheerstrake, the connection developing the same strength as the screw. Where, however, they are set up fore and aft on stays, the pad should have a shackle-eye for pin, as 'thwartship movement is not then desirable, and the shackle-eye will permit of a smaller diameter pin being used.

In proportioning screws under one inch in diameter, an allowance of about 20 per cent must be added to the area of metal at root of thread, as compensation for the loss of strength sustained in cutting the screw. Screws should be smeared with tallow and coated with a canvas cover.

Sheerpoles. — It is usual to fit a rod to the heads of turnbuckles to shrouds connecting and supporting the heads in their relative position, and preventing the screws from slacking back. In small vessels it may be from \(\frac{3}{4}''\) to \(\frac{4}{3}''\) diameter, seized to each head with seizing wire. Where heavy rigging is dealt with, the sheerpole is bolted through the heart of turnbuckle, and bosses jumped on to form receptacles for belay pins.

Ratlines — Are commonly made of hemp or wire rope, seized at outer shrouds and passing around the others in a clove bitten,

and spaced about 24 inches apart. Rope, however, is being fast displaced by iron rod ratlines, seized with wire to shrouds.

ROPES.

Manila and hemp, tarred and white, are the materials from which most ship's ropes are made. As its name indicates, "Manila" hails from the Philippines, and is made from the fibre of the wild banana. Hemp rope is made from the fibre of the hemp plant, the Russian variety being most generally used. Tow lines are sometimes made of coir, which is manufactured from the tough fibrous husk of the cocoanut. In referring to ropes, the circumference always denotes the size.

Manila. — All running ropes and those used for sundry work on shipboard are made of Manila, as hemp, though stronger when white, is not pliable enough. It is usual to make it of 3 strands, although 4-stranded or shroud-laid rope is also made; and for yacht work, 4-strand Manila is best, as it is smaller in diameter for a given strength, besides being neater.

Manila is of greater strength than tarred hemp, and stands the weather much better than the untarred or white hemp, although

not so strong as the latter.

The following tables give strengths and weights of Manila, hemp, and coir ropes: —

CARGO BLOCKS.

CHAPTER III.

TACKLES.

When ropes are reeved through blocks to multiply the power it is proposed to apply, the combined gear constitutes what is known as a tackle. The principle of the block and tackle is the distribu-

100 LB8. PLUS POWER 50 LBS TO BALANCE SINGLE WHIP

tion of weight in various points of support. the mechanical advantage derived depending entirely upon flexibility and tension of the rope, and the number of sheaves in the moving block, hence by tackles the power APPLIED TO RAISE is to the weight as the number of parts attached to the moving block, therefore (1) divide the weight to be raised by the number of parts leading "to," "from." or "made fast" to the

moving block, and the quotient is the power required to produce equilibrium - omitting friction.

(2) Divide the weight to be raised by the power proposed, and the quotient is the number of sheaves in, or parts attached to, the moving block.

It should be noted that the upper block of a tackle has to bear the weight to be raised, and the power applied to lift it. No power is gained by increasing the diameter of the sheaves, but by doing so you

decrease friction.

Fig. 347.

In arranging the blocks for a purchase, note that the hauling part, where possible, should lead from the moving block, as by so arranging, the power is increased.

200 LBQ WHIP UPON WHIP

Fig. 348.

Tackles are named variously, sometimes as threefold, fourfold, etc., referring to the number of ropes rove; and as guy-tackles, sheet-tackles, etc., or by a distinctive name, whose derivation in most cases is obscure, like Spanish burton, etc.

A single whip and whip-upon-whip are shown by Figs. 272 and 273 and their mechanical advantage indicated.

trictly the single whip is not really a tackle, as no mechanical antage is gained. If we reverse the arrangement, and instead fixing the block, we make one end of the rope fast and haul

on the other after it is rove through the block, which is now movable, we have a tackle with the power applied doubled.

The next simplest form to the foregoing is the gun-tackle purchase, shown by Fig. 274, which consists of two single blocks, one movable and the other fixed. In the diagram, the power is shown as being applied to the fixed pulley, which results in doubling the power only. If, however, the order be reversed, and the rope becketed to the lower block, from which the hauling end would now lead, we should increase the power gained so that 150 lbs. could be sustained in equilibrium by the application of 50 lbs.

In all tackles the hauledon block has not only to support the load pendant PURCHASE on it, but also the power DOUBLE required to lift the load.

> The luff-tackle purchase shown in Fig. 275, is also known as a watch-

150 LRR.

BO LBA

GUN

TACKLE

L twofold purchase consists of two double eks, and has a ratio of power to weight of quarter, when hauled on from the fixed k, and of one fifth when from the moving зk.

L threefold purchase comprises a pair of treble blocks with echanical advantage of one sixth leading from the fixed block, one seventh when hauled on from the moving block.

ig. 276 shows a single Spanish burton, which is composed two single blocks with the tackle reeved as shown, This purchase has the same power as the luff tackle, but less friction. It is a handy and powerful purchase, used for doing odd jobs.

The double Spanish burton is made up of a luff-tackle and a whip, with the standing parts toggled on together to the becket of the lower single block. It has the same power,

but with much less friction, as a threefold purchase hauled on from the moving block.

Relieving tackles are usually two or three-fold purchases, having the fixed block shackled on end of spare tiller, and the hauling block made fast on the quarter. These tackles are used for steering, in case of break-down, and need only to be figured for the steamer going at slightly over half speed.

A tackle may be attached to the hauling part of another tackle, and so multiply the powers

of which they are comprised.

of sheaves for the power required should be used, and all superfluous fair-

As an example of the application of the foregoing notes on purchases

leads dispensed with, as each additional sheave fitted for that purpose absorbs power.

to the finding of a suitable tackle for a given load, let us take the case of relieving tackles on tiller. The twisting moment on the rudder head is first calculated by the rule given on page 106, which we shall assume to be 150,000 inch-lbs. With a spare tiller 50 inches long from centre of stock to shackle BURTON pin, we should have a net load of 3,000 lbs.

200 LBS.

SINGLE

Fig. 351.

SPANISH

BURTON

to move, and it is proposed to use a fourfold purchase (i.e., 2 double blocks) for the purpose, which will increase the load by four tenths (4 sheaves by one tenth of the load each for friction), making the actual load to

be operated 3,000 + 1,200 = 4,200 lbs. The moving block being on the tiller head, it is not practicable to haul from it, therefore we have only 4 parts at this block. Dividing the total load by four ropes, we get 1,050 lbs. (.47 ton) tension on each fall. With

a factor of safety of 41, using the best Manila rope, we get the equivalent circumference from the formula

$$\sqrt{\text{tension} \times 10} = \sqrt{.47 \times 10} = 21''$$

say 21", as the manufactured sizes grade by quarters.

The size of the double blocks to take the rope would be 7 inches, obtained by the rule on p. 394, and it would require four men to

handle the hauling part.

It is desired to lift a weight of 12 tons with a ship's derrick, and the maximum load on the winch must not exceed 5 tons; required the purchase, size of steel wire rope falls and blocks? Owing to the heavy load dealt with in this case, the factor of safety need not exceed 5. The hauling part of falls to be led through a leading block at heel of derrick.

Load to be raised			•		•	12	tons
Friction of 5 sheaves .		• '				6	"
Derrick gear						.4	"
Total load to overcome			_		_	18.4	"

As the load on the winch may not exceed 5 tons, the purchase should be $\frac{18.4}{4.6}$ = four parts in the falls — a twofold purchase.

A factor of safety of 5 having previously been decided upon, we get for the breaking stress $4.6\times 5=23$ tons, and the equivalent circumference of special flexible steel wire rope, per table = 3 inches circ., which will require two double blocks with sheaves 13½ inches in diameter. It should be noted that the maximum tension comes on the hauling part in hoisting, but on the standing part in lowering.

The stress on topping lift, allowing for friction of one sheave, and power applied is equal to 9.4 tons, requiring special flexible

steel wire rope of 31" circumference.

A fourfold purchase rove with Manila 4" circ. having two 12" double blocks, with wide mortise and the hauling part taken from the moving block, will be suitable for the load of 9.4 tons minus the power applied, i.e., 84 tons.

The following tables give the strength of tackles and the breaking stress from actual test of hooks and shackles, fitted by the

makers to the various sizes of blocks.

The proper working load for new Manila ropes is \(\frac{1}{3}\) of the breaking stress. Of course, first grade Manila will develop a greater strength than what is shown by the accompanying tables of tackles, which are based on the strength of new rope adopted by the manufacturers, and consequently should be worked to when figuring the safe working load.

Rule to find the equivalent circumference of Manila rope for a given working load or tension (in tons) on one part of a fall, based on a factor of safety of 3:—

Circumference = $\sqrt{10 \times \text{tension}}$ which is very easily memorized. Inversely, the safe working load for a given circumference of Manila will be $\frac{\text{Circ.}^2}{10} = \text{safe load}.$

SECTION V.

CHAPTER I.

EQUIPMENT. .

In a modern steamship the Equipment, as understood by the classification societies, comprises that part of a vessel's outfit which relates to the handling of the ship and the safety of her complement, and in Lloyd's Register is represented by the numeral "1" after the character. Under this heading are included, anchors, chains, hawsers, boats, steering gear, windlass, and the requirements of the Board of Trade Regulations or the United States Inspection Laws.

Lloyd's Equipment.

The equipment as regards anchors, chains, hawsers, warps, etc. is regulated by the number produced by the sum of the measurements in feet arising from the addition of the half-moulded breadth of the vessel at the middle of the length, the depth from the upper part of the keel to the top of the upper deck beams (with the normal camber), and the girth of the half midship frame section of the vessel, measured from the centre line at the top of the keel to the upper deck stringer plate, multiplied by the length of the vessel for a one, two, and three decked vessel and for a spar decked vessel. For a vessel having a complete awning deck, or a continuous shade deck, the equipment number is to be increased one-eighth beyond that given by the measurements defined above to the main deck.

For a steam vessel with a partial awning deck, poop, top gallant forecastle, bridge house or a raised quarter deck the equipment number is to be increased beyond that for a flush or spar-decked vessel by that proportion of the addition made for a complete awning deck (i.e., one-eighth) which the combined length of the erection bears to the length of the vessel. Where erections are fitted upon erections, the equipment number is to be correspondingly increased in the same proportion. (Sect. 39 of Lloyd's Rules.)

As an example of the method of applying the foregoing rule, let us take the case of a 3-deck vessel, having a complete shelter-deck, and a bridge superstructure with houses erected on it. This type will clearly exemplify all of the requirements of the rule, as we shall calculate the numeral firstly for a 3-deck vessel, to which we will then add one eighth for the complete shelter-deck, afterwards increasing it by the proportion that the length of bridge superstructure bears to the length of ship (or how much of another eighth we shall take), and finally resolving the area of the deck erections or superstructure into an equivalent length of vessel enclosing the same area, and adding its proportionate value.

Example: — Required the equipment numeral for a three-decked vessel having a complete shelter-deck on which is built a superstructure having deck houses on top:—

```
Dimensions:
                          550' \times 65' \times 41' to shelter deck
                                      33.5' to upper deck
    Length of superstructure . . 250'
    Size of deck houses . . . 100' \times 40'
             =4,000 \text{ sq. ft.} = \frac{4000}{65} = 61.5' \text{ equivalent length}
    Depth (to U.DK+161" camber), 34.85' }
                                     63.00′ \
    Half girth . . . . .
                                    130.35
    Length .
                                     \times 550'
                                 71,692.5
    Add 1 for complete shelter
         deck . . . . . .
                                  8,961.5
    Add proportion of 1 repre-
        sented by 250' of super-
                                  4.073.1
         structure . . . . .
    Add proportion of 1 repre-
         sented by 61.5' equiva-
         lent length of houses . 1,001.8
    Equipment number . . 85,728.9
```

The preceding "Table 22" of Lloyd's Rules shows the requirements of that Society for steam vessels based on the above rule.

MOORING SWIVEL.

Fig. 353.

N.B. In all chain cable details the unit for determining the dimensions is the size of cable iron.

ADMIRALTY CABLE REQUIREMENTS.

Samples shall be taken by the Overseer indiscriminately for testing from every description of iron included in any one invoice, provided the number of bars, etc., so included does not exceed 50, and if above that number, one for every 50 or portion of 50 of each description. The samples may be tested to show the fibre, strength, ductility, and other qualities of the iron, and if not found satisfactory, the lot from which they are taken may be rejected.

In cases where the quantity of each size is small, and the total quantity of bars of all sizes does not exceed 50 No., one sample only need be tested, provided that all the bars represented thereby are supplied by one maker, and that the Overseer is satisfied as to the quality of the iron; the sample for testing shall be selected by him, and the acceptance or rejection of the batch shall depend upon the result of the tests.

The samples of every description of iron shall have an ulti-

mate tensile strength respectively: -

Of not less than 23 tons to the square inch of section, for sizes under 21 inches:

Of not less than 22½ tons to the square inch of section, for sizes from 2½ to 2½ inches, both sizes inclusive; and Of not less than 22 tons to the square inch of section, for sizes above 2½ inches;

with an elongation of 20 per cent, in a length of 8 inches, for all sizes of iron.

Tensile tests, if not made on the premises of the Iron Manufacturer, shall be applied at a public testing house at the Contractors' expense, and in the presence of the Overseer.

Forge Test, Cold.

Every bar of 1-inch diameter and above shall admit of bending cold to the same radius as the end of the link for which it is to be used thus:

it is to be used, thus:

Bars under 1 inch to admit of bending cold, thus:

A sample shall be notched and bent, thus:
to show the fibre and quality of the iron, which is to be entirely satisfactory to the Overseer.

Forge Test, Hot.

Bars shall be punched with a punch one-third the diameter of the bar, at a distance of one and one-half diameters from the

Ł

end of the bar. The hole may then be drifted out to one and one-quarter times the diameter of the bar. The side of the hole may then be split, and the ends must admit of turning back without fracture, thus:

The whole of the articles, including the annealed crucible cast steel or forged steel stud pins of the cables, and the tinned steel pins, etc., shall be made only of material approved by the Overseer. The iron

for the articles enumerated in Schedules II and III shall be also well hammered and rolled, and of quality approved by the Overseer.

Anchor shackle bolts shall be made of blooms at least twice worked, and not of bar iron. The square links and shackles, together with the swivels and bolts, shall be worked or drawn out under hammers of sufficient weight, and the welds or shuts shall be made in the most perfect and solid manner. No iron shall be used in which the brand-mark is so deeply cut as to unduly weaken the section, or is so situated as to make unsatisfactory work in forming the link, and the Contractors shall make arrangements for storing the Admiralty cable iron separately from all other cable iron.

All the stud pins of the chain cable shall be marked on one side with the name or initials of the Contractors, and on the other side with the date of the year of delivery into store. several lengths of each chain cable, and mooring, pendant or bridle chain, and the joining shackles and large shackles to be connected therewith, shall be marked as follows, viz.: — The end links of the lengths of the cable with a distinguishing number, and the broad arrow; the joining shackles and anchor shackles with the same distinguishing number, the broad arrow. and the initials of the Contractors; the mooring and other swivels and splicing shackles, on their largest part, with a distinguishing number, the broad arrow, and the initials of the Contractors; and the splicing shackles and swivels with the date of the year of delivery into store, in addition. Cables and all cable gear will be received for the first four months of each year with the last year's date on the stud pins.

Tests. — The whole of the articles enumerated in Schedules I, II and III, shall be subjected, before delivery, to the proof strains prescribed in the Specification and Tables herewith, and to the following breaking test, which shall be first applied.

Chain Cables, Bridle and Pendant.—A sample of three links taken from each length of chain cable, or each bridle and pendant chain, shall be subject to tensile strain until it breaks. The links shall be cut out at the public testing machine in the presence of the Overseer, when practicable. Should it break under a less strain than 50 per cent in excess of the proof strain, the entire length of which that portion is a sample shall be rejected.

Cables and gear which pass the proving and breaking tests shall be minutely examined by the Overseer, and any flaws or defects which he may point out shall be remedied to his satisfaction before the cables and gear are forwarded to the yards.

The cables, etc., shall be cleaned sufficiently to permit of the

Overseer guaranteeing the absence of flaws or defects.

The breaking strain of the several sizes of cables shall not fall short of the

above proof strains, with 50 per cent added.

Note. — The above proof strains are equivalent to the following strains per circular \(\frac{1}{2} \) inch of iron, viz., \(3\) inch, 504 lbs.; \(3\) inch, 536.5 lbs.; \(3\) inch, 567 lbs.; \(2\) inch and under, \(630 \) lbs. The table can be used for calculating the weight of cable in lengths less than 12\) isthoms.

The Naval Constructor

CHAPTER II.

BOATS.

THE American and the British requirements for boats carried by foreign-going steamships are practically identical, but for vessels employed in the home trade there is much dissimilarity. The following notes, therefore, where they refer to the number of boats to be carried, apply only to ocean-going steamships.

Many of the boats carried on steamships are good examples of what a boat should not be. The contractor should not only supply the boat-builder with the dimensions of the boats required, but also with an outline of the mid section, more particularly in the case of life-boats and dinghies. In many cases these boats have much too quick a rise of floor line, making them dangerous to step into in the light condition. In addition, their scantlings are often inadequate for working boats exposed at all times to the extremes of weather. With a view to supplying a good guide as to what are wholesome proportions for the various classes of boats hung under davits, the subjoined diagram has been prepared by the writer. It is based on a long experience in designing and building these craft.

When outline plans of boats are prepared, the following points should be noted:—

Minimum clear distance between thwarts, 2'2''. Centre of row crutches = 10" abaft aft edge of thwarts. Top of thwarts or benches = 9" below bottom of row crutch. In single-banked boats stroke is always starboard. Breadth of transom = $\frac{2}{3}$ rds. midship top breadth (except in gigs). Rabbet of transom = half the stern depth above base. Siding of hog = twice the siding of keel. Moulding of hog = .4 of the siding. Scarphs of keel, etc. = $4\frac{1}{2}$ times the siding.

Sails.—The sail area may with advantage be based on the midship section area measured to underside of thwarts multiplied by 12. $A \times 12 = \text{sail}$ area.

Scantlings.—The scantlings may be as given in the table which shows the requirements for boats of the Royal Navy, or these may be modified by the designer in accordance with his own experience.

Slings.—Inspectors should insist that all sling plates and lifting rings be tested. The following table shows the tests to which these fittings are usually subjected for the various classes of hoats.

CHAPTER III.

BRITISH RULES FOR STEAMSHIPS CARRYING PASSENGERS, BOATS AND LIFE-SAVING APPLIANCES.

- (a) Ships of Division A, Class 1, shall carry boats placed under davits, fit and ready for use, and having proper appliances for getting them into the water, in number and capacity as prescribed by the table in the appendix to these Rules (see page 433); such boats shall be equipped in the manner required by, and shall be of the description defined in, the General Rules appended hereto.
- (b) Masters or owners of ships of this class claiming to carry fewer boats under davits than are given in the table must declare before the collector or other officers of customs, at the time of clearance, that the boats actually placed under davits are sufficient to accommodate all persons on board, allowing 10 (ten) cubic feet of boat capacity for each adult person, or "statute adult."
- (c) Not less than half the number of boats placed under davits, having at least half the cubic capacity required by the tables, shall be boats of Section A or Section B. The remaining boats may also be of such description, or may, in the option of the shipowner, conform to Section C, or Section D, provided that not more than two boats shall be of Section D.
- (d) If the boats placed under davits in accordance with the table do not furnish sufficient accommodation for all persons on board, then additional wood, metal, collapsible or other boats of approved description (whether placed under davits or otherwise), or approved life-rafts, shall be carried. One of these boats may be a steam launch; but in that case the space occupied by the engines and boilers is not to be included in the estimated cubic capacity of the boat.

Subject to the provisions contained in paragraph (f) of these rules, such additional boats or rafts shall be of at least such carrying capacity that they and the boats required to be placed under davits by the table provide together in the aggregate, in vessels of 5,000 tons gross and upwards, three fourths, and in vessels of less than 5,000 tons gross, one half, more than the minimum cubic contents required by column 3 of the table. For this purpose 3 cubic feet of air-case in the life-raft is to be estimated as 10 cubic feet of internal capacity. Provided always that the rafts will accommodate all the persons for which they are to

be certified under the Rules, and also have 3 cubic feet of air-case for each person.

All such additional boats or rafts shall be placed as conveniently for being available as the ship's arrangements admit of, having regard to the avoidance of undue encumbrance of the ship's deck,

and to the safety of the ship for her voyage.

(e) In addition to the life-saving appliances before mentioned, ships of this class shall carry not less than one approved life-buoy for every boat placed under davits. They shall also carry approved life-belts, or other similar approved articles of equal buoyancy suitable for being worn on the person, so that there may be at least one for each person on board the ship.

(f) Provided, nevertheless, that no ship of this class shall be required to carry more boats or rafts than will furnish sufficient

accommodation for all persons on board.

General Rules.

Boats.—All boats shall be constructed and properly equipped as provided by these Rules, and all boats and other life-saving appliances are to be kept ready for use to the satisfaction of the Board of Trade. Internal buoyancy apparatus may be constructed of wood, or of copper or yellow metal, of not less than 18 ounces to the superficial foot or of other durable material.

Section A. A boat of this section shall be a life-boat, of whale-boat form, properly constructed of wood or metal, having for every 10 cubic feet of her capacity, computed as in Rule 2, at least one cubic foot of strong and serviceable enclosed air-tight compartments, so constructed that water cannot find its way into them. In the case of metal boats, an addition will have to be made to the cubic capacity of the air-tight compartments, so as to give them buoyancy equal to that of the wooden boat.

Section B. A boat of this section shall be a life-boat, of whale-boat form, properly constructed of wood or metal, having inside and outside buoyancy apparatus together equal in efficiency to the buoyancy apparatus provided for a boat of Section A. At least one-half of the buoyancy apparatus must be attached to the

outside of the boat.

Section C. A boat of this section shall be a life-boat, properly constructed of wood or metal, having some buoyancy apparatus attached to the inside and (or) outside of the boat equal in efficiency to one-half of the buoyancy apparatus provided for a boat of Section A or Section B. At least one-half of the buoyancy apparatus must be attached to the outside of the boat.

Section D. A boat of this section shall be a properly con-

structed boat of wood or metal.

Section E. A boat of this section shall be a boat of approved construction, form and material, and may be collapsible.

Cubic Capacity.—The cubic capacity of a boat shall be deemed to be her cubic capacity, ascertained (as in measuring ships for tonnage capacity) by Simpson's rule; but as the application of that rule entails much labor, the following simple plan, which is approximately accurate, may be adopted for general purposes, and when no question requiring absolute correct adjustment is raised:—

Measure the length and breadth outside and the depth inside. Multiply them together and by .6; the product is the capacity of the boat in cubic feet. Thus, a boat 28 feet long, 8 feet 6 inches broad, and 3 feet 6 inches deep, will be regarded as having a capacity of $28 \times 8.5 \times 3.5 = 499.8$, or 500 cubic feet. If the oars are pulled in rowlocks, the bottom of the gunwale of the rowlock is to be considered the gunwale of the boat for ascertaining her depth.

Number of Persons for Boats.—The number of persons a boat of Section A shall be deemed fit to carry shall be the num-

ber of cubic feet, ascertained as above, divided by 10.

The number of persons a boat of Section B, Section C, Section D, or Section E shall be deemed fit to carry, shall be the number of cubic feet, ascertained as per rule, divided by 8. The space in the boat shall be sufficient for the seating of the persons carried in it, and for proper use of the oars.

Appliances for Lowering Boats. — Appliances for getting a boat into the water must fulfil the following conditions: - Means are to be provided for speedily, but not necessarily simultaneously or automatically, detaching the boats from the lower blocks of the davit tackles; the boats placed under davits are to be attached to the davit tackles and kept ready for service; the davits are to be strong enough and so spaced that the boats can be swung out with facility; the points of attachment of the boats to the davits are to be sufficiently away from the ends of the boats to insure their being easily swung clear of the davits; the boat's chocks are to be such as can be expeditiously removed; the davits, falls, blocks, eyebolts, rings, and the whole of the tackling are to be of sufficient strength: the boat's falls are to be long enough to lower the boat into the water with safety when the vessel is light. The life-lines shall be fitted to the davits, and be long enough to reach the water when the vessel is light; and hooks are not to be attached to the lower tackle blocks.

Equipments for Collapsible or other Boats, and for Life-Rafts.—In order to be properly equipped, each boat shall be provided as follows:—

(a) With the full single-banked complement of oars, and two spare oars.

(b) With two plugs for each plug-hole, attached with lanyards or chains, and one set and a half of thole pins or crutches, attached

to the boat by sound lanyards.

- (c) With a sea-anchor, a baler, a rudder and a tiller, or yoke lines, a painter of sufficient length, and a boat-hook. The rudder and the baler to be attached to the boat by sufficiently long lanyards, and kept ready for use. In boats where there may be a difficulty in fitting a rudder, a steering oar may be provided instead.
- (d) A vessel to be kept filled with fresh water shall be provided for each boat.
- (e) Life-rafts shall be fully provided with a suitable approved equipment.

Additional Equipments for Boats of Section A and Section B.—In order to be properly equipped, each boat of Sections A and B, in addition to being provided with all the requisites laid down in Rule, shall be equipped as follows, but not more than four boats in any one ship require to have this outfit, and where boats of Sections A or B are carried in lieu of boats of Sections C or D, this additional outfit need not be insisted on:—

(a) With two hatchets or tomahawks, one to be kept in each end of the boat, and to be attached to the boat by a lanyard.

(b) With mast or masts, and with at least one good sail, and proper gear for each.

 (\bar{c}) With a line becketted round the outside of the boat and

securely made fast.

(d) With an efficient compass.

(e) With one gallon of vegetable or animal oil, and a vessel of an approved pattern, for distributing it in the water in rough weather.

(f) With a lantern trimmed, with oil in its receiver sufficient to burn eight hours.

Number of Persons for Life-Rafts. — The number of persons that any approved life-raft for use at sea shall be deemed to be capable of carrying, shall be determined with reference to each separate pattern approved by the Board of Trade; provided always, that for every person so carried there shall be at least three cubic feet of strong and serviceable enclosed air-tight compartments, constructed so that water cannot find its way into them. Any approved life-raft of other construction may be used, provided that it has equivalent buoyancy to that hereinbelieve

described. Every such approved life-raft shall be marked in such a way as to plainly indicate the number of adult persons it can carry.

Buoyant Apparatus.— Approved buoyant apparatus shall be deemed sufficient, so far as buoyancy is concerned, for a number of persons, to be ascertained by dividing the number of pounds of iron which it is capable of supporting in fresh water by 32. Such buoyant apparatus shall not require to be inflated before use, shall be of approved construction, and marked in such a way as plainly to indicate the number of persons for whom it is sufficient.

Life-Belts.—An approved life-belt shall mean a belt which does not require to be inflated before use, and which is capable at least of floating in the water for 24 hours with 15 pounds of iron suspended from it. Life-belts are to be cut out 2 inches under the arm-pits, and fitted so as to remain securely in their place when put on.

Life-Buoys.—An approved life-buoy shall mean either: (a) A life-buoy built of solid cork, capable of floating in water for at least 24 hours with 32 pounds of iron suspended from it; (b) A strong life-buoy of any other approved pattern or material, provided that it is capable of floating in water for at least 24 hours with 32 pounds of iron suspended from it, and provided also that it is not stuffed with rushes, cork shavings, or other shavings, or loose granulated cork or other loose material, and does not require infiation before use.

All life-buoys shall be fitted with beckets securely seized, and not less than two of them shall be fitted with life-lines 15 fathoms in length.

Position of Life-Buoys and Life-Belts. Water-tight Compartments.—All life-buoys and life-belts shall be so placed as to be readily accessible to all persons on board, and so that their position may be known to those for whom they are intended,

When ships of any class are divided into efficient water-tight compartments to the satisfaction of the Board of Trade, they shall only be required to carry additional boats, rafts and buoyant apparatus of one-half the capacity required by these Rules, but the exemption shall not extend to life-jackets or similar approved articles of equal buoyancy suitable to be worn on the person.

The table referred to in the foregoing Rules, showing the minimum number of boats to be placed under davits and their minimum cubic contents, follows:—

BOAT CAPACITY FOR STEAMERS.

(BRITISH LAW.)

Note. — Where in ships already fitted the required cubic contents of boats placed under davits is provided, although by a smaller number of boats than the minimum required by this table, such ships shall be regarded as complying with the rules as to boats to be carried under davits.

In case of vessels under 200 tons gross tonnage, the capacity of any boat to be supplied should not be less than 125 feet. If, however, in any case this rule be found impracticable, a discretion may then be exercised by the Board of Trade.

In cases where a small vessel is unable to carry more than one boat, a discretion may be exercised by the Board of Trade; but whenever one boat only is carried, there must be proper provision to enable it to be placed readily in the water on either side of the ship.

Capacity and Form of Life-Boats. - As regards the boats of Sections A, B, C, and D, Rule 1, the surveyors will see that the requirements of the Rules are observed, and that the capacity of the boats, and the number of persons they are fit to carry, are ascertained by Rules 2 and 3 (page 430). In measuring boats the length and breadth are to be regarded as the extreme dimensions measured to the outside of the plank. The number of persons for which a boat is to be passed is, however, subject to the further condition that the space in the boat shall be sufficient for the seating of them all, and the proper use of the oars. That this requirement is fulfilled must be ascertained by practical experiment in all cases before a declaration is granted, unless one or more boats in a ship are of the same pattern, when only one of such boats need be tested. Life-boats (except those of Section C) should be built whale-boat fashion, both ends alike. which have been fitted with boats previous to the Rules coming into force, square-sterned boats need not be condemned if fitted with the required amount of buoyancy, but all life-boats of Sections A and B subsequently supplied, or supplied to new ships, must be built whale-boat fashion. All collapsible boats, and all boats whether collapsible or not, if constructed of any material other than wood or metal, must be in accordance with a pattern approved by the Board of Trade before they are passed as a portion of the life-saving appliances required by the Rules.

Stowage of Boats. — All boats required by the Rules to be placed under davits are to be kept fit and ready for use; and when they are swung inboard and resting on the chocks, the chocks are to be so constructed that the boat can be at once swung outboard without requiring to be lifted by the tackles—i.e., it shall not be necessary to take more than the weight of the boat.

The manner in which the additional boats, not requiring to be

placed under davits, are to be stowed, will vary in different ships, but they must be stowed to the satisfaction of the surveyors, so as to be as readily available for use as is practicable, having due consideration to the circumstances mentioned in the Rules.

In all cases where boats are stowed on skids, a batten and space platform of about 2½" planks should be fitted from skid to skid, under and alongside the boat, when being launched forward or aft, and as a platform for the men.

Equipments.—The equipments for all boats are provided for in the Rules, and surveyors are to see that the requirements are carefully complied with. The painters for boats are not to be less than 20 fathoms in length.

When the Rules require a life-boat of Section C to be carried, and owners choose to provide a boat of Section A or B, the additional equipments required by General Rule 6 for boats of Section A and Section B need not be insisted on.

Rudder. — In some of the collapsible boats it is difficult to fit a rudder; in this case a steering oar properly fitted may be passed instead.

Buoyancy.—The buoyancy of life-boats of Section B must be partly inside and partly outside the boat, and a boat in which it is wholly inside or wholly outside shall not be passed as a boat of Section B.

In the case of life-boats of Section C, one-half the buoyancy must be outside the boat; the remainder may be either inside or outside, or partly inside and partly outside.

The inside buoyancy for boats of Sections A, B, and C, must consist of strong and serviceable enclosed air-tight compartments, such that water cannot find its way into them.

The outside buoyancy for boats of Section B must consist of solid cork covered with canvas, and painted and attached to the outer skin of the boat to the satisfaction of the surveyors, both as regards its position and also as regards its attachment. No other material is to be used unless expressly sanctioned by the Board of Trade. The outside buoyancy must be equal to at least half the buoyancy required for boats of Section A, and the inside and outside buoyancy together must equal in efficiency the buoyancy required for a boat of Section A.

To effect this 1.25 cubic feet of cork is to be considered as

equivalent to 1 cubic foot of air-case.

The foregoing remarks apply to outside buoyancy for boats of Section C, excepting that the total buoyancy is only required to be half that of boats of Section A or Section B. When the solid cork is not permanently attached to the side of the boat in such a

manner that moisture cannot collect between the two surfaces, it will require to be removed every time a declaration is granted to ascertain (1) whether the cork is becoming sodden; (2) whether moisture is collecting between the cork and the skin of the boat, and in that way rotting the wood. The consideration (2) will not apply to metal boats.

Air-Cases, Material and Construction.—Air-cases are required by the Rules to be constructed of wood, or of copper or yellow metal of not less than 18 ounces to the superficial foot, or of other durable material.

The average weight of 18 ounce copper air-cases is about 5 pounds per cubic foot, and if air-cases of other material exceed this weight, the cubic capacity of the air-cases must be correspondingly increased.

As yellow metal in time becomes extremely brittle, copper is far preferable. Zinc is not durable material, and should not be passed; neither should galvanized iron or steel cases be passed for new boats.

A note should be made in each district of all ships whose boats are already filled with galvanized iron or steel air-cases, with a view to their being frequently inspected. Steel or iron air-cases previously passed of less thickness than 21 ounces are not to be rejected so long as they continue in good condition.

Copper and yellow metal air-cases are to be made with proper hook joints not less than three-eighths of an inch in width, hammered well down and soldered, and no other joint is to be passed unless specially approved by the Board of Trade.

The cases are not to exceed four feet in length; they are to be substantially enclosed with wood, which is to be close-jointed so as to cover any exposed part of the air-case, and the wood forming the top is not to be less than one inch in thickness.

The coverings in the boats over the air-cases should be secured with brass screws, so as to enable the cases to be removed without difficulty for examination, and no air-case which is not enclosed from the outer shell of the boat should be passed.

Spaces filled with or containing any material are not to be deemed air-spaces unless specially approved by the Board of Trade.

Copper or yellow metal air-cases must not be carried in contact with the skin of the metal boats.

Where boats not required by the Rules to be fitted with air-cases are so fitted, as, for instance, in some of the collapsible or semi-collapsible boats, these provisions as to air-cases need not be insisted upon.

Steam Launches, etc., Carried by Steamships. — In the cases of launches er other boats propelled by steam power, which

are carried as part of the additional boat equipment required by the Rules made under the provisions of the Merchant Shipping Act, an inspection of the boat, machinery, and boilers, and of the mounting and fitting thereof, should be made. Steam launches must not be passed as a part of the boat equipment required to be under davits.

In case of any vessel provided with a steam launch or boat in addition to the boat capacity required under the Rules, the surveyors need not interfere unless they have reason to believe that there is some defect in the boat, machinery, or boiler, or in the fittings or arrangement thereof, which might be dangerous to life.

Boats Already Supplied.—In carrying these instructions into effect, surveyors are to be careful not to interfere unnecessarily with boats supplied before November, 1890, but in the case of new boats coming under survey for the first time, as well as in all cases in which the fittings of the boats require renewal, the Rules contained in these instructions are to be strictly adhered to.

Appliances for Lowering Boats. — These appliances must be in accordance with Rule 4, of the General Rules, and must, in the surveyor's opinion, be such as not to endanger human life. They should be tested at each survey for renewal of a passenger certificate.

The question of determining whether the requirements of the Rules respecting appliances for lowering boats are complied with in the case of any particular kind of gear coming under the surveyor's notice, shall be left to the principal officers of the districts.

In order to insure uniformity of practice, each principal officer, who may pass any particular disengaging gear, should request the maker to supply 50 copies of the plans and specifications for distribution among the surveyors in the several districts. These copies should be sent to the Board of Trade by the Principal Officer, together with his report upon the gear. No certificates of approval for disengaging gear will be issued.

The Principal Officer should also report to the Board of Trade when any particular disengaging gear has been inspected and deemed unsatisfactory or unsafe, and should explain fully in such report the details which, in his opinion, render it undesirable. No formal certificate of approval will, however, be granted by the Board of Trade or their officers for any special kind of gear.

Life-Rafts, Buoyant Apparatus. — No part of the gear which is intended to bear the weight of the boat must be made of cast iron, and life-rafts are to be approved by the Board of Trade; they are to be supplied with a suitable equipment to the satisfac-

tion of the surveyors, and this must include a sea-anchor, not less than 20 fathoms of hawser, and oars in proportion to the size of the raft.

The number of persons that any approved life-raft for use at sea is to be deemed capable of carrying is the number that the raft is able to seat safely, provided always that for every person so carried there are at least three cubic feet of strong and serviceable enclosed air-tight compartments.

Approved buoyant apparatus is to be deemed sufficient for a number of persons to be ascertained by dividing the number of pounds of iron which it is capable of supporting in fresh water by 32, provided also that the sides and ends of the apparatus shall afford a space of one horizontal foot for each person for whom it is certified, and that a line for the people to cling to is properly becketted all round it. Such buoyant apparatus shall not require to be inflated before use, and shall be of approved construction.

Marking. - Surveyors will note that rafts and buoyant apparatus shall be marked in such a way as to plainly indicate the number of adult persons for which they are deemed sufficient. Plates will be supplied by the Board of Trade to be screwed on to the woodwork of both rafts and buoyant apparatus, indicating this number; and forms of demand (surveys 116 for rafts and 116a for buoyant apparatus) for plates, to be filled up and returned to the Board of Trade, will be issued for the use of the Principal Officer. No raft or buoyant apparatus is to be regarded as finally approved until the marking-plate has been affixed.

Air-Cases of Rafts, etc. — The instructions in the case of lifeboats apply equally to life-rafts and buoyant apparatus, so far as the length, weight and enclosure of the air-cases are concerned. excepting that as life-rafts and buoyant apparatus are only intended to be used in cases of extreme need, and are consequently not exposed to the same wear and tear as the life-boats, a minimum weight of 16 ounces, copper or yellow metal, may be passed.

Life-Belts. - No life-belt is to be passed that is not capable of floating in fresh water for 24 hours with 15 pounds of iron suspended from it. It should be cut out 2 inches under the armpits, and fitted so as to remain securely in its place when put on. When any other material than solid cork is used for buoyancy, it must be specially approved by the Board of Trade. All new lifebelts should be fitted with adjustable shoulder-straps.

It is desirable that notices should be posted indicating the place of stowage of any belts which are not plainly visible to pas-

sengers.

Life-Buoys. — No life-buoy stuffed with rushes or with cork shavings or other shavings, or granulated cork, or any loose material, is to be passed. All cork life-buoys are to be built of solid cork, and fitted with lines becketted and securely seized to the life-buoy, and none are to be passed that will not float for 24 hours in fresh water with 32 pounds of iron suspended from them. If life-buoys are not made of solid cork, the pattern and material must be approved by the Board of Trade. No contrivance is to be passed as a life-buoy that requires inflation before use. Lifebuoys are to be secured by a toggle and becket, or any other similar method, so that they can be quickly released; they must not be lashed or seized to the rail or any part of the vessel, but must be kept so as to be ready for use at a moment's notice in case of an emergency.

Not less than two of the life-buoys, one on each side of the ship, are to be fitted with life-lines 15 fathoms in length.

Oil-distributing Apparatus. — Vessels for distributing oil are to be to the satisfaction of the surveyors, and are to be so constructed as to distribute the oil evenly and gradually on the surface of the water.

CHAPTER IV.

UNITED STATES NAVIGATION LAWS RELAT-ING TO BOATS AND LIFE-SAVING APPLIANCES.

THE British requirements as to the build of boats, number of oars, life-lines, and the rule for calculating the capacities of life-boats, are similar to the American regulations, excepting that for river steamers the capacity is divided by 7 to give the number of persons carried,

Boat Ladders.—Where ladders or steps are necessary to enable passengers on board to escape conveniently to the life-boats, such steps shall be provided and placed on each side of the steamer, with manropes of suitable size and of sufficient length to reach the water; and one of the means of escape from one deck to another shall be near the stern of the vessel.

Relieving Tackle. — Extra steering apparatus for all steamers carrying passengers, consisting of relieving tackles or tiller, must be provided.

Metal Life-Boats must be constructed of good iron or other suitable metal not less in thickness than 18 B.W.G.

Davits.—All life-boats must, if possible, be carried on cranes or davits; but if impossible so to carry all the life-boats required, the remainder must be stowed near at hand, so as to be easily and readily launched when required.

River Steamers. — Steamers navigating rivers only (except ferry-boats, canal-boats, and towing-boats, of less than 50 tons) must have one good substantial boat. The cubic capacity of such boat as found by the rule given on p. 444 divided by 7 will determine the number of persons to be carried.

Freight, Canal, and Towing Steamers.—Freight, canal, and towing steamers of less than 50 tons must be equipped with boats or rafts, as, in the opinion of the inspectors, may be necessary, in case of disaster, to secure the safety of all persons on board.

Excursions by Permit. — Steamers making an excursion under a permit must have at least one life-boat, and shall be equipped with other life-boats, or their equivalents, as, in the

judgment of the inspectors, will best secure the safety of all persons on board in case of disaster.

Automatic Plug. — All metal life-boats hereafter built shall be furnished with an automatic plug.

River Passenger Steamers.—Passenger steamers navigating rivers (excepting steamers of 100 gross tons and under, hereinafter provided for) must be supplied, in addition to the boat required in the paragraph "River Steamers," with life-boats in proportion to their tonnage, as follows:

```
Steamers over 100 and not over 300 gross tons 1 boat.

Steamers over 600 and not over 600 gross tons 2 boats.

Steamers over 900 and not over 1,200 gross tons 3 boats.

Steamers over 1,200 gross tons 4 boats.

Steamers over 1,200 gross tons 5 boats.
```

Aggregate Capacity.— The aggregate capacity of life-boats on steamers navigating the Red River of the North and rivers whose waters flow into the Gulf of Mexico and their tributaries, shall not be less than 120 cubic feet to each boat for the number of boats as given in the table; and for life-boats on steamers navigating other rivers than those named, the aggregate capacity shall not be less than 180 cubic feet to each boat as given in the table; and where smaller life-boats are employed for either class of river steamers, their aggregate capacity shall not be less than the aggregate capacity of the larger boats; provided, however, that river steamers required, under the table, to carry more than two boats, may, where the owners prefer to do so, supply the boat capacity above that number with a good, substantial life-raft or rafts, such raft or rafts to be of an aggregate carrying capacity not less than that of the boats so omitted.

Capacity may Equal Complement. — No steamer embraced in the foregoing section shall be required to have more life-boats, or of a greater capacity, than sufficient to carry the passengers allowed by the certificate of inspection (including the crew). One of the life-boats, unless exempted by the supervising inspector, must be made of metal.

Life-Boats for Ocean Steamers.—The total capacity of lifeboats, or of life-boats and life-rafts, on steamers navigating the ocean (except steamers of 100 gross tons and under, hereinafter provided for), shall not be less than the capacity given, according to tonnage, in the following table:

BOAT CAPACITY FOR OCEAN STEAMERS.

(AMERICAN LAW.)

		(dros	s Tonn	AGE						OF BOATS IN CUBIC FEET
Steame											
100	and	not o	ver	200							540

14,500	44	4.6		15,000	1						10,170
15,000	- 67								1		10,395

Note. — Not more than one-third of the boat capacity required on ocean steamers may be substituted by its equivalent in approved life rafts or approved collapsible (folding) life-boats.

These boats must be of suitable dimensions, and each not less than 180 cubic feet capacity. (For good proportions of boats, see diagram on p. 421.)

LIFE-BOATS FOR STEAMERS NAVIGATING NORTHWESTERN LAKES, BAYS, AND SOUNDS.

		GROSS TO	NNAGE.			No. of Boats.	CAPACITY OF BOATS.
Steamer	s ov	er:			 _		Cu. Ft.

2,000	44	66	2,500.		.	9	1,620
2,500	44	66	3,000.		.	10	1,800
3,000	66	66	3,500.		. 1	11	1,980
3,500	66	66	4,000.		.	12	2,160
4,000	46	66	4,500.			13	2,340
4,500	44	4.6	5,000.		.	14	2,835
5,000	44	44	5,500.		.	15	3,330

Note on Table.—Steamers above 5,500 gross tons shall be furnished with an additional boat of not less than 495 cubic feet capacity for each additional 500 tons burden, or fraction thereof; or if the owners or agents prefer, two boats may be used; provided, the aggregate capacity shall be the same as the one boat described.

These boats shall be substantially built with reference to the trade in which the steamer is engaged, and shall not be of less dimensions than 20 ft. \times 5 ft. \times 3 ft.,* unless, where smaller lifeboats are employed, their aggregate capacity shall equal the aggregate capacity of the larger boats; provided, however, that no steamer shall be required to have more life-boats than sufficient to carry the passengers she is allowed by the certificate of inspection, together with her officers and crew.

Not more than one third of the boat capacity required on lake, bay, and sound steamers may be substituted by its equivalent in approved life-rafts or approved collapsible (folding) life-boats.

^{*} For good proportions, see diagram on page 421.

Marking of Boats.—All wood boats required on steam-vessels shall have branded or cut on the stem thereof the net cubic feet contents of such boats, figured as follows:

Multiply the outside length, outside width, and inside depth together and the product by 6, and divide the product by 10 for ocean, lake, bay, or sound steamers; and for river steamers, divide the product by 7; the quotient will be the number of persons such a boat is allowed to carry.

Example.—The carrying capacity of a boat 20 feet in length, 5 feet 6 inches in breadth, and 2 feet 3 inches deep, will be determined as under:

For ocean, lake, bay, or sound steamers,

$$\frac{20 \times 5.5 \times 2.25 \times .6}{10} = \frac{148.5}{10} = 15 \text{ persons.}$$

For river steamers, same boat, $\frac{148.5}{7} = 21$ persons.

Metal boats shall have net cubic feet measurement painted on stem in black letters and figures not less than $\frac{3}{4}$ inch high on a white ground.

Every life-raft shall have stencilled on it in a conspicuous place (the number of persons it can carry, as determined by) the net cubic feet contents as per ratio in the following paragraph:

Life-Raft Capacity. — All life-rafts and floats shall have an actual buoyancy of 187½ lbs. upon oceans for every person allowed, and 156 lbs. upon lakes, bays, sounds, and rivers for every person allowed. Such life-rafts and floats must be suitably equipped with life-lines and oars.

All rubber and canvas rafts shall be kept inflated at all times.

Life-Floats. — When wooden life-floats are required on steamvessels, in compliance with law they shall be at least of the following dimensions, or other proper dimensions of equal cubical capacity, viz., 4 feet in length, 14 inches in breadth, and 2 inches in thickness. These floats shall be made of white pine wood, or any other wood not exceeding white pine * in weight per cubic foot.

Drags, or Floating Anchors. — Drags, or floating anchors, shall be constructed so as to be capable of being compactly stowed near the head of the ship. (For a detail of these anchors, see p. 363.)

Steamers navigating the ocean must be provided with at least one drag, of area as follows: — For steamers of 400 gross tons and

* What is known as white pine in the States is called yellow pine in the British Isles.

under, not less than 25 superficial feet; for steamers of over 400 gross tons, the area of drag shall not be less than that determined by adding to 25 square feet one square foot for each additional 25 gross tons above 400 tons.

Example. — The area of a drag on a vessel of 1,000 tons will equal: —

 $25 + \frac{1,000 - 400}{25} = 49$ square feet.

Steamers of over 5,000 tons gross may be equipped with two or more drags, provided the total area is not less than that required by this rule. Steamers whose routes do not extend off anchorage are not required to have drags, or floating anchors, on board. (A table giving areas for sea-anchors based on the above rule is

given on p. 362.)

Every life-preserver adjustable to the body of a person shall be made of good, sound cork blocks or other suitable material. with belts and shoulder straps properly attached, and shall be constructed so as to place the cork underneath the shoulders and around the body of the person wearing it, the shoulder straps to be sewed on at least eight inches apart on the back of the preserver, and sewed together at an angle where they cross the body, and must also have a strap across the breast from one shoulder strap to the other, sewed fast at one end and with a buttonhole at the other, with a button on shoulder strap to which the cross piece can be buttoned, and all belt life-preservers shall be not less than 54 inches in length, measurement from end to end around the body. And it shall be the duty of the inspectors to see by actual examination that every such life-preserver contains at least six pounds of good cork, which shall have a buoyancy of at least four pounds to each pound of cork. Inspectors are further required to see such life-preservers are distributed throughout the cabins, staterooms, berths, and other places convenient for passengers on such steamer; and there shall be a printed notice posted in every cabin and stateroom, and in conspicuous places about the decks, informing passengers of the location of lifepreservers and other life-saving appliances, and of the mode of applying or adjusting the same. Cork cushions, when constructed of good, sound cork blocks or other suitable material, with belts and shoulder straps properly attached, said cushions to contain not less than six pounds of cork, when passed by local inspectors, may be used in lieu of life-preservers on small pleasure steamers.

Barges towed by steamers and carrying passengers on regular "night routes" shall have a life-preserver for each passenger; and, in addition thereto, shall be supplied with a yawl boat, ten

buckets and three axes.

Every sea-going steamer and every steamer navigating the great Northern and Northwestern lakes carrying passengers shall have not less than three water-tight cross bulkheads. Such bulkheads shall reach to the main deck in single-decked vessels, otherwise to the deck next below the main deck. For wooden hulls they shall be fastened to suitable framework, which framework must be securely attached to the hull and caulked. For iron hulls they shall be well secured to the framework of the hulls and strengthened by stanchions of angle iron placed not more than two feet from centre to centre. One of the bulkheads must be placed forward and one abaft of the engines and boilers.

The third or collision bulkhead must be placed not nearer than five feet from the stem of the vessel. Iron bulkheads must be made not less than one-quarter of an inch in thickness, and wooden bulkheads must be of equal strength and covered with iron plates not less than one-sixteenth of an inch in thickness.

Steam ferry-boats of 50 tons burden and over must be supplied with life-boats as in the judgment of the inspector will best promote the security of life on board of such vessels in case of disaster, according to the average number of passengers carried per trip.

Table of dimensions of boats for passenger steamers of 100 gross tons and under, navigating lakes, bays, sounds, and rivers, other than the Red River of the North and rivers whose waters flow into the Gulf of Mexico. Boats of other dimensions of equivalent cubical capacity may be used:—

Number of Tons (Gross).				NUMBER OF BOATS.	Dimensions.					FACTOR.	CONTENTS.
					Length.	Brea	adth.	De	pth.	Ā	CON
Steamers over:					Ft.	Ft.	In.	Ft.	In.		Cu. Ft.

30	"	"	50	1	16	5	6	2	3	.7	138.6
10	"		30	1	14	5	0	2	2	.7	106.1
0	"		10	1	14	4	6	2	0	.7	88.2

The cubical capacity of life-boats on steamers of 100 gross tons and under, navigating the Red River of the North and rivers whose

waters flow into the Gulf of Mexico, shall be as follows, measured as per example in Section 2, Rule III:—

	CUBIC FEET.			
Steamers over 50 and not over 100 gross tons			105	
Steamers over 30 and not over 50 gross tons			92	
Steamers over 10 and not over 30 gross tons			71	
Steamers of 10 gross tons and under	•		· 60	

The life-boat on steamers between 50 and 100 tons must be in addition to the working boat required by Section 6 of this rule.

The boat for passenger steamers of 10 tons and less may be dispensed with if such steamer is provided with metallic air chambers, placed under the seats and in the ends of said vessel, of sufficient capacity to float the inert weight of said vessel including her boilers and machinery; otherwise the life-boat referred to in the above table must be either carried or towed at all times when being navigated with passengers on board; and all such vessels referred to in this section shall also be provided with one life-preserver for every person which the inspection certificate shall allow them to carry, including officers and crew.

All open steam launches or other steam-vessels of five tons burden or less, used for pleasure purposes only, will not be required to carry a life-boat. Such steamers when licensed to carry passengers may dispense with the life-boat when such vessels are provided with metallic air chambers placed under the seats and in the ends of said vessels, of sufficient capacity to float the inert weight of said vessel, including her boilers and machinery; and such vessels shall also be provided with one life-preserver for every person which the inspection certificate shall allow them to carry, including the officers and crew; and every such steam-vessel carrying fifteen passengers or less shall carry at least two fire buckets and one axe.

All steam-vessels certificated as ocean, lake, bay, or sound at their annual inspection after the adoption of this rule (except vessels of 100 tons and under, inspected under the provisions of Section 4426, Revised Statutes, and freight and towing steamers, inspected under the provisions of Section 4427, Revised Statutes) shall be provided with a line-carrying projectile and the means of propelling it, such as may have received the formal approval of the Board of Supervising Inspectors.

All inland passenger steamers are required to be provided with fire buckets, barrels, axes, as follows:

Gross Tons.	BARRELS.	BUCKETS.	Axes.
All steamers not over 10 tons		2	1
All steamers over 10 tons and not over 25 tons		4	1
All steamers over 25 tons and not over 50 tons	· 1	6	2
All steamers over 50 tons and not over 100 tons	1	8	2
All steamers over 100 tons and not over 200 tons	2	18	4
All steamers over 200 tons and not over 500 tons	4	24	6
All steamers over 500 tons and not over 1000 tons	8	35	R
All steamers over 1000 tons	8	50	10

For tug, tow, freight, and small ferry steamers:

Gross Tons.	BARRELS.	Buckets.	Axes.
All steamers not over 10 tons		2	1
All steamers over 10 tons and not over 25 tons		4	1
All steamers over 25 tons and not over 50 tons	1	6	2
All steamers over 50 tons and not over 100 tons	1	8	2
All steamers over 100 tons and not over 200 tons	1	12	2
All steamers over 200 tons and not over 500 tons	2	15	3
All steamers over 500 tons and not over 1000 tons	3	20	4
All steamers over 1000 tons, not less than	4	25	5

Provided, however, That tanks of suitable dimensions and arrangements, or buckets in sufficient number may be substituted for barrels on all vessels. Five buckets shall be considered as equivalent to one barrel.

Fire buckets, barrels, or tanks, must be constantly filled with water, and in such positions on board as shall be most convenient for extinguishment of fire.

All axes must be so located as to be readily found in time of need, must not be used for general purposes, and must be kept in

good condition.

All hay, straw, or baled shavings carried on deck of passenger steamers shall be covered with a tarpaulin while on board.

Boilers.—All boilers shall have a clear space of at least 8 inches between the underside of the cylindrical shell and the floor or keelson.

All boilers shall have a clear space at the back and ends thereof of 2 feet opposite the back connection door; provided, that on vessels constructed of iron or steel with metal bulkheads the distance between back connection doors and such metal bulkheads shall not be less than 16 inches.

Donkey Boiler.—Every sea-going steamer carrying passengers shall be supplied with an auxiliary or donkey boiler of sufficient capacity to work the fire pumps, and such boiler shall not be placed below the lower decks except on single-deck vessels.

CHAPTER V.

INTERNATIONAL RULES OF 1897.*

Preliminary Definitions.—In the following rules every steam-vessel which is under sail and not under steam is to be considered a sailing-vessel, and every vessel under steam, whether under sail or not, is to be considered a steam-vessel.

The word "steam-vessel" shall include any vessel propelled by

machinery.

A vessel is "under way" within the meaning of these rules when she is not at anchor, or made fast to the shore, or aground.

Lights, etc. — The word "visible" in these rules when applied to lights shall mean visible on a dark night with a clear atmosphere.

The rules concerning lights shall be complied with in all weathers from sunset to sunrise, and during such time no other lights which may be mistaken for the prescribed lights shall be exhibited.

Steam-Vessel's Masthead Light. — A steam-vessel, when under way, shall carry: (a) On or in front of the foremast, or if a vessel without a foremast, then in the fore part of the vessel, at a height above the hull of not less than twenty feet, and if the breadth of the vessel exceeds twenty feet, at a height above the hull not less than such breadth, so, however, that the light need not be carried at a greater height above the hull than forty feet, a bright, white light, so constructed as to show an unbroken light over an arc of the horizon of twenty points of the compass, so fixed as to throw the light ten points on each side of the vessel, namely, from right ahead to two points abaft the beam on either side, and of such a character as to be visible at a distance of at least five miles.

Steam-Vessel's Side-Lights.— (b) On the starboard side a green light so constructed as to show an unbroken light over an arc of the horizon of ten points of the compass, so fixed as to throw the light from right ahead to two points abaft the beam on the starboard side, and of such a character as to be visible at a distance of at least two miles.

(c) On the port side a red light so constructed as to show an unbroken light over an arc of the horizon of ten points of the compass, so fixed as to throw the light from right ahead to two

* Subscribed to by the Maritime Nations.

points abaft the beam on the port side, and of such a character as to be visible at a distance of at least two miles.

(d) The said green and red side-lights will be fitted with inboard screens projecting at least three feet forward from the light, so as to prevent these lights from being seen across the bow. (Fig. 286.)

Fig. 864.

Steam-Vessels' Range Lights.— (e) A steam-vessel when under way may carry an additional white light similar in construction to the light mentioned in subdivision (a). These lights shall be so placed in line with the keel that one shall be at least fifteen feet higher than the other, and in such a position with reference to each other that the lower light shall be forward of the upper one. The vertical distance between these lights shall be less than the horizontal distance.

Steam-Vessels when Towing.—A steam-vessel when towing another vessel shall, in addition to her side-lights, carry two bright white lights in a vertical line one over the other, and not less than six feet apart; and when towing more than one vessel shall carry an additional bright white light six feet above or below such light, if the length of the tow measuring from the stern of the towing vessel to the stern of the last vessel towed exceeds six hundred feet. Each of these lights shall be of the same construction and character, and shall be carried in the same position as the white light mentioned in Article 2 (a), excepting the additional light, which may be carried at a height of not less than fourteen feet above the hull.

Such steam-vessels may carry a small white light abaft the funnel or aftermast for the vessel towed to steer by, but such light shall not be visible forward of the beam.

Special Lights.—(a) A vessel which from any accident is not under command shall carry at the same height as the white light mentioned in Article 2 (a), where they can be best seen, and if a steam-vessel in lieu of that light, two red lights, in a vertical line one over the other, not less than six feet apart, and of such a character as to be visible all around the horizon at a distance of at least two miles; and shall by day carry in a vertical line one over the other, not less than six feet apart, where they can be best seen,

two black balls or shapes, each two feet in diameter.

(b) A vessel employed in laying or in picking up a telegraph cable shall carry in the same position as the white light mentioned in Article 2 (a), and if a steam-vessel in lieu of that light, three lights in a vertical line one over the other, not less than six feet apart. The highest and lowest of these lights shall be red, and the middle light shall be white, and they shall be of such a character as to be visible all around the horizon at a distance of at least two miles. By day she shall carry in a vertical line one over the other, not less than six feet apart, where they can be best seen, three shapes not less than two feet in diameter, of which the highest and the lowest shall be globular in shape and red in color, and the middle one diamond in shape and white.

(c) The vessels referred to in this article, when not making way through the water, shall not carry the side-lights, but when mak-

ing way shall carry them.

(d) The lights and shapes required to be shown by this article are to be taken by other vessels as signals that the vessel showing them is not under command and cannot therefore get out of the way.

These signals are not signals of vessels in distress and requiring

assistance. Such signals are contained in Article 31.

Lights for Sailing-Vessels and Vessels in Tow. — A sailing-vessel under way and any vessel being towed shall carry the same lights as are prescribed by Article 2 for a steam-vessel under way, with the exception of the white lights mentioned therein, which they shall never carry.

Lights for Small Vessels.—Whenever, as in the case of small vessels under way during bad weather, the green and red lights cannot be fixed, these lights shall be kept at hand, lighted and ready for use; and shall on the approach of or to other vessels, be exhibited on their respective sides in sufficient time to prevent collision, in such manner as to make them most visible, and so that the green light shall not be seen on the port side, nor the red light on the starboard side, nor, if practicable, more than two points abaft the beam on their respective sides. To make the use of these portable lights more certain and easy, the lanterns

containing them shall each be painted outside with the color of the light they respectively contain, and shall be provided with proper screens.

Lights for Small Steam and Sail Vessels and Open Boats.—Steam-vessels of less than forty, and vessels under oars or sails of less than twenty tons gross tonnage, respectively, and rowing boats, when under way, shall not be required to carry the lights mentioned in Article 2 (a), (b), and (c), but if they do not carry them they shall be provided with the following lights:—

First: Steam-vessels of less than forty tons shall carry:

(a) In the fore part of the vessel or on or in front of the funnel, where it can be best seen, and at a height above the gunwale of not less than nine feet, a bright white light constructed and fixed as prescribed in Article 2 (a), and of such a character as to be visible at a distance of at least two miles.

(b) Green and red side-lights constructed and fixed as prescribed in Article 2 (b) and (c), and of such a character as to be visible at a distance of at least one mile, or a combined lantern showing green and red light from right ahead to two points abaft the beam on their respective sides. Such lanterns shall be carried not less than three feet below the white light.

Second: Small steamboats, such as are carried by sea-going vessels, may carry the white light at a less height than nine feet above the gunwale, but it shall be carried above the combined light mentioned in subdivision one (b).

Third: Vessels under oars or sails of less than twenty tons shall have ready at hand a lantern with a green glass on one side and a red glass on the other side, which, on the approach of or to other vessels, shall be exhibited in sufficient time to prevent collision, so that the green light shall not be seen on the port side, nor the red light on the starboard side.

Fourth: Rowing boats, whether under oars or sail, shall have ready at hand a lantern showing a white light which shall be temporarily exhibited in sufficient time to prevent collision.

The vessels referred to in this article shall not be required to carry the lights prescribed by Article 4 (a) and Article 11, last paragraph.

Lights for Pilot Vessels. — Pilot vessels, when engaged on their station on pilotage duty, shall not show the lights required for other vessels, but shall carry a white light at the masthead, visible all around the horizon, and shall also exhibit a flare-up light or flare-up lights at short intervals, which shall never exceed fifteen minutes.

On the near approach of or to other vessels they shall have their side-lights lighted, ready for use, and shall flash or show them at

short intervals, to indicate the direction in which they are heading; but the green light shall not be shown on the port side, nor

the red light on the starboard side.

A pilot vessel of such a class as to be obliged to go alongside of a vessel to put a pilot on board, may show the white light instead of carrying it at the masthead, and may instead of the colored lights above mentioned, have at hand, ready for use, a lantern with green glass on one side and red glass on the other, to be used as prescribed above.

Pilot vessels, when not engaged on their station on pilotage duty, shall carry lights similar to those of other vessels of their

tonnage.

A steam pilot vessel when engaged on her station on pilotage duty and in the waters of the United States, and not at anchor, shall, in addition to the lights required for all pilot boats, carry at a distance of eight feet below her white masthead light a red light, visible all around the horizon, and of such character as to be visible on a dark night with a clear atmosphere at a distance of at least two miles, and also the colored side-lights required to be carried by vessels when under way.

When engaged on her station on pilotage duty and in waters of the United States, and at anchor, she shall carry, in addition to the lights required for all pilot boats, the red light above mentioned,

but not the colored side-lights.

When not engaged on her station on pilotage duty, she shall carry the same lights as other steam-vessels.

Lights, etc., of Fishing Vessels.— (Article 9, act of August 19, 1890, was repealed by act of May 28, 1894, and Article 10, act of March 3, 1885, was re-enacted in part by act of August 13, 1894, and is reproduced here in part as Article 9. It will be the

object of further consideration by the maritime powers.)

Fishing vessels of less than twenty tons net registered tonnage, when under way and not having their nets, trawls, dredges, or lines in the water, shall not be obliged to carry the colored sidelights; but every such vessel shall in lieu thereof have ready at hand a lantern with a green glass on the one side and red glass on the other side, and on approaching to or being approached by another vessel, such lanterns shall be exhibited in sufficient time to prevent collision, so that the green light shall not be seen on the port side, nor the red light on the starboard side.

Lights for Fishing Vessels on European Ccasts.—The following portion of this article applies only to fishing vessels and boats when in the sea off the coast of Europe lying north of Cape Finisterre:—

(a) All fishing vessels and fishing boats of twenty tons net regis-

tered tonnage or upward, when under way and when not having their nets, trawls, dredges, or lines in the water, shall carry and

show the same lights as other vessels under way.

(b) All vessels when engaged in fishing with drift-nets shall exhibit two white lights from any part of the vessel where they can be best seen. Such lights shall be placed so that the vertical distance between them shall not be less than six feet and more than ten feet, and so that the horizontal distance between them, measured in a line with the keel of the vessel, shall not be less than five feet and not more than ten feet. The lower of these two lights shall be the more forward, and both of them shall be of such a character and contained in lanterns of such construction as to show all around the horizon, on a dark night with a clear atmosphere, for a distance of not less than three miles.

(c) All vessels when trawling, dredging, or fishing with any kind of drag-nets, shall exhibit, from some part of the vessel where they can be best seen, two lights. One of these lights shall be red, and the other shall be white. The red light shall be above the white light, and shall be at a vertical distance from it of not less than six feet and not more than twelve feet; and the horizontal distance between them, if any, shall not be more than ten feet. These two lights shall be of such a character and contained in lanterns of such construction as to be visible all around the horizon, on a dark night with a clear atmosphere, the white light to a distance of not less than three miles, and the red light of not less than two miles.

(d) A vessel employed in line fishing, with her lines out, shall carry the same lights as a vessel engaged in fishing with driftness.

(e) If a vessel, when fishing with a trawl, dredge, or any kind of drag-net, becomes stationary in consequence of her gear getting fast to a rock or other obstruction, she shall show the light and

make the fog signal for a vessel at anchor.

(f) Fishing vessels may at any time use a flare-up in addition to the lights which they are by this article required to carry and show. All flare-up lights exhibited by a vessel when trawling, dredging, or fishing with any kind of drag-net, shall be shown at the after-part of the vessel, excepting, if that vessel is hanging by the stern to her trawl, dredge, or drag-net, they shall be exhibited from the bow.

(g) Every fishing vessel, when at anchor between sunset and sunrise, shall exhibit a white light, visible all around the horizon

at a distance of at least one mile.

(h) In a fog a drift-net vessel attached to her nets, and a vessel when trawling, dredging, or fishing with any kind of drag-net, and a vessel employed in line fishing with her lines out, shall, at

short intervals, to indicate the div at a blast with her foging; but the green light shall the red light on the stark A vessel which is being A pilot vessel of suc' m her stern to such last-mena vessel to put a pile ap light. of carrying it at k shown by this article may be but in such case the lantern shall creened that it shall throw an undithe horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of twenty and the horizon of the horizon of twenty and the horizon of twenty and the horizon lights above me with green glas the horizon of twenty points of the as prescribed points from right aft on each side of the points at a distance of at least one mile. Such searly as practicable on the same level as Pilot ves duty, shal' tonnage. A ste duty 2 A vessel under 150 feet in length, when at shall forward, where it can best be seen, but at a a di the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in the light, in th a description at a discount and unbroken νĬſ a clear, uniform, and unbroken a clear, uniform, and unbroken a distance of at least one gį of 150 feet or upwards in length, when at anchor, shall A forward part of the vessel, at a height of not less than test and not exceeding forty feet above the hull, one such freely and st or near the stern of the vessel, and at such a height hight shall be not less than fifteen feet lower than the forward that it shall be not less than fifteen feet lower than the forward hight, another such light. The length of a vessel shall be deemed to be the length appearing in her certificate of registry. ressel aground in or near a fairway shall carry the above Beht or lights and the two red lights prescribed by Article 4 (a).

UNITED STATES INLAND RULES.*

Steam-Vessels' Masthead Lights.—A steam-vessel when under way shall carry (n) or or in front of the foremast, or, if a vessel without a foremast, then in the fore part of the vessel, a bright white light so constructed as to show an unbroken light over an arc of the horizon of twenty points of the compass, so fixed as to throw the light ten points on each side of the vessel, — namely, from right ahead to two points abait the beam on either side, and of such a character as to be visible at a distance of at least five miles.

^{*} For all vessels navigating harbors, rivers and inland waters of the United States, except the Great Lakes.

Steam-Vessels' Side-Lights. — (b) On the starboard side a green light so constructed as to show an unbroken light over an arc of the horizon of ten points of the compass, so fixed as to throw the light from right ahead to two points abaft the beam on the starboard side, and of such character as to be visible at a distance of at least two miles.

(c) On the port side a red light so constructed as to show an unbroken light over an arc of the horizon of ten points of the compass, so fixed as to throw the light from right ahead to two points abaft the beam on the port side, and of such a character as to be visible at a distance of at least two miles. (See Fig. 286.)

(d) The said green and red side-lights shall be fitted with inboard screens projecting at least three feet forward from the light, so as to prevent these lights from being seen across the bow.

Steam-Vessels' Range-Lights.—(e) A sea-going steam-vessel when under way may carry an additional white light similar in construction to the light mentioned in subdivision (a). These two lights shall be so placed in line with the keel that one shall be at least fifteen feet higher than the other, and in such a position with reference to each other that the lower light shall be forward of the upper one. The vertical distance between these lights shall be less than the horizontal distance.

(f) All steam-vessels (excepting sea-going vessels and ferry-boats) shall carry in addition to green and red lights required by Article 2 (b) (c), and screens as required by Article 2 (d), a central range of two white lights, the after light being carried at an elevation at least fifteen feet above the light at the head of the vessel. The head-light shall be so constructed as to show an unbroken light through twenty points of the compass, — namely, from right ahead to two points abaft the beam on either side of the vessel, and the after light so as to show all around the horizon.

Steam-Vessels when Towing.—A steam-vessel when towing another vessel shall, in addition to her side-lights, carry two bright white lights in a vertical line one over the other, not less than three feet apart; and when towing more than one vessel shall carry an additional bright white light three feet above or below such lights, if the length of the tow measuring from the stern of the towing vessel to the stern of the last vessel towed exceeds six hundred feet. Each of these lights shall be of the same construction and character, and shall be carried in the same position as the white light mentioned in Article 2 (a), or the after range-light mentioned in Article 2 (f).

Such steam-vessels may carry a small white light abaft the funnel or aftermast for the vessel towed to steer by, but such light shall not be visible forward of the beam. intervals of not more than two minutes, make a blast with her foghorn and ring her bell alternately.

Lights for an Overtaken Vessel.—A vessel which is being overtaken by another shall show from her stern to such last-men-

tioned vessel a white light or flare-up light.

The white light required to be shown by this article may be fixed and carried in a lantern, but in such case the lantern shall be so constructed, fitted, and screened that it shall throw an unbroken light over an arc of the horizon of twenty points of the compass; namely, for six points from right aft on each side of the vessel, so as to be visible at a distance of at least one mile. Such light shall be carried as nearly as practicable on the same level as the side-lights.

Anchor Lights.—A vessel under 150 feet in length, when at anchor, shall carry forward, where it can best be seen, but at a height not exceeding twenty feet above the hull, a white light, in a lantern so constructed as to show a clear, uniform, and unbroken light visible all around the horizon at a distance of at least one mile.

A vessel of 150 feet or upwards in length, when at anchor, shall carry in the forward part of the vessel, at a height of not less than twenty feet and not exceeding forty feet above the hull, one such light, and at or near the stern of the vessel, and at such a height that it shall be not less than fifteen feet lower than the forward light, another such light.

The length of a vessel shall be deemed to be the length appear-

ing in her certificate of registry.

A vessel aground in or near a fairway shall carry the above light or lights and the two red lights prescribed by Article 4 (a).

UNITED STATES INLAND RULES.*

Steam-Vessels' Masthead Lights.—A steam-vessel when under way shall carry (a) on or in front of the foremast, or, if a vessel without a foremast, then in the fore part of the vessel, a bright white light so constructed as to show an unbroken light over an arc of the horizon of twenty points of the compass, so fixed as to throw the light ten points on each side of the vessel,—namely, from right ahead to two points abaft the beam on either side, and of such a character as to be visible at a distance of at least five miles.

^{*} For all vessels navigating harbors, rivers and inland waters of the United States, except the Great Lakes.

Steam-Vessels' Side-Lights.—(b) On the starboard side a green light so constructed as to show an unbroken light over an arc of the horizon of ten points of the compass, so fixed as to throw the light from right ahead to two points abaft the beam on the starboard side, and of such character as to be visible at a distance of at least two miles.

(c) On the port side a red light so constructed as to show an unbroken light over an arc of the horizon of ten points of the compass, so fixed as to throw the light from right ahead to two points abaft the beam on the port side, and of such a character as to be visible at a distance of at least two miles. (See Fig. 286.)

(d) The said green and red side-lights shall be fitted with inboard screens projecting at least three feet forward from the light, so as to prevent these lights from being seen across the bow.

Steam-Vessels' Range-Lights.—(e) A sea-going steam-vessel when under way may carry an additional white light similar in construction to the light mentioned in subdivision (a). These two lights shall be so placed in line with the keel that one shall be at least fifteen feet higher than the other, and in such a position with reference to each other that the lower light shall be forward of the upper one. The vertical distance between these lights shall be less than the horizontal distance.

(f) All steam-vessels (excepting sea-going vessels and ferry-boats) shall carry in addition to green and red lights required by Article 2 (b) (c), and screens as required by Article 2 (d), a central range of two white lights, the after light being carried at an elevation at least fifteen feet above the light at the head of the vessel. The head-light shall be so constructed as to show an unbroken light through twenty points of the compass, —namely, from right ahead to two points abaft the beam on either side of the vessel, and the after light so as to show all around the horizon.

Steam-Vessels when Towing.—A steam-vessel when towing another vessel shall, in addition to her side-lights, carry two bright white lights in a vertical line one over the other, not less than three feet apart; and when towing more than one vessel shall carry an additional bright white light three feet above or below such lights, if the length of the tow measuring from the stern of the towing vessel to the stern of the last vessel towed exceeds six hundred feet. Each of these lights shall be of the same construction and character, and shall be carried in the same position as the white light mentioned in Article 2 (a), or the after range-light mentioned in Article 2 (f).

Such steam-vessels may carry a small white light abaft the funnel or aftermast for the vessel towed to steer by, but such light shall not be visible forward of the beam.

Lights for Sailing-Vessels and Vessels in Tow. - A sailing-vessel under way or being towed shall carry the same lights as are prescribed by Article 2 for a steam-vessel under way, with the exception of the white lights mentioned therein, which they shall never carry.

Lights for Ferry-Boats, Barges, and Canal-Boats in Tow. — The supervising inspectors of steam-vessels and the Supervising Inspector-General shall establish such rules to be observed by steam-vessels in passing each other, and as to the lights to be carried by ferry-boats and by barges and canal-boats when in tow of steam-vessels, not inconsistent with the provisions of this Act, as they from time to time may deem necessary for safety, which rules, when approved by the Secretary of Commerce and Labor, are hereby declared special rules duly made by local authority, as provided for in Article 30 of Chapter 802 of the Laws Two printed copies of such rules shall be furnished to of 1890. such ferry-boats and steam-vessels, which rules shall be kept posted up in conspicuous places in such vessels.

Lights for Small Vessels. — Whenever, as in the case of vessels of less than ten gross tons under way during bad weather, the green and red side-lights cannot be fixed, these lights shall be kept at hand, lighted and ready for use; and shall, on the approach of or to other vessels, be exhibited on their respective sides in sufficient time to prevent collision, in such manner as to make them most visible, and so that the green light shall not be seen on the port side, nor the red light on the starboard side, nor, if practicable, more than two points abaft the beam on their respective To make the use of these portable lights more certain and easy, the lanterns containing them shall each be painted outside with the color of the light they respectively contain, and shall be provided with proper screens.

Rowing boats, whether under oars or sail, shall have ready at hand a lantern showing a white light, which shall be temporarily

exhibited in sufficient time to prevent collision.

Lights for Pilot Vessels. - Pilot vessels, when engaged on their stations on pilotage duty, shall not show the lights required by other vessels, but shall carry a white light at the masthead, visible all around the horizon, and shall also exhibit a flare-up light or flare-up lights at short intervals, which shall never exceed fifteen minutes.

On the near approach of or to other vessels they shall have their side-lights lighted, ready for use, and shall flash or show them at short intervals, to indicate the direction in which they are heading; but the green light shall not be shown on the port side, nor the

red light on the starboard side.

A pilot vessel of such a class as to be obliged to go alongside of a vessel to put a pilot on board, may show the white light instead of carrying it at the masthead, and may, instead of the colored lights above mentioned, have at hand, ready for use, a lantern with green glass on the one side and red glass on the other, to be used as prescribed above.

Pilot vessels, when not engaged on their station on pilotage duty, shall carry lights similar to those of other vessels of their

tonnage.

A steam pilot vessel when engaged on her station on pilotage duty and in waters of the United States, and not at anchor, shall, in addition to the lights required for all pilot boats, carry at a distance of eight feet below her white masthead light a red light, visible all around the horizon, and of such a character as to be visible on a dark night with a clear atmosphere at a distance of at least two miles, and also the colored side-lights required to be carried by vessels when under way.

When engaged on her station on pilotage duty and in waters of the United States, and at anchor, she shall carry, in addition to the lights required for all pilot boats, the red light above men-

tioned, but not the colored side-lights.

When not engaged on her station on pilotage duty, she shall carry the same lights as other steam-vessels.

Lights, etc., of Fishing Vessels.—Fishing vessels of less than ten gross tons, when under way and not having their nets, trawls, dredges, or lines in the water, shall not be obliged to carry the colored side-lights; but every such vessel shall, in lieu thereof, have ready at hand a lantern with a green glass on one side and a red glass on the other side, and on approaching to or being approached by another vessel, such lantern shall be exhibited in sufficient time to prevent collision, so that the green light shall not be seen on the port side, nor the red light on the starboard side.

All fishing vessels and fishing boats of ten gross tons or upward, when under way and when not having their nets, trawls, dredges, or lines in the water, shall carry and show the same lights as

other vessels under way.

All vessels when trawling, dredging, or fishing with any kind of drag-nets or lines, shall exhibit, from some part of the vessel where they can be best seen, two lights. One of these lights shall be red, and the other shall be white. The red light shall be above the white light, and shall be at a vertical distance from it of not less than six feet and not more than twelve feet; and the horizontal distance between them, if any, shall not be more than ten feet.

These two lights shall be of such a character and contained in lanterns of such construction as to be visible all around the horizon. the white light at a distance of not less than three miles, and the red light not less than two miles.

Lights for Rafts, or Other Craft, not Provided for .-Rafts, or other water craft, not herein provided for, navigating by hand power, horse power, or by the current of the river, shall carry one or more good lights, which shall be placed in such manner as shall be prescribed by the Board of Supervising Inspectors of Steam-Vessels.

Lights for an Overtaken Vessel. — A vessel which is being overtaken by another, except a steam-vessel with an after rangelight showing all around the horizon, shall throw from her stern to such last-mentioned vessel a white or a flare-up light.

Anchor Lights. - A vessel under 150 feet in length, when at anchor, shall carry forward, where it can be best seen, but at a height not exceeding twenty feet above the hull, a white light in a lantern so constructed as to show a clear, uniform, and unbroken light visible all around the horizon at a distance of at least one mile.

A vessel of 150 feet or upwards in length, when at anchor, shall carry in the forward part of the vessel, at a height of not less than twenty feet and not exceeding forty feet above the hull, one such light, and at or near the stern of the vessel, and at such a height that it shall not be less than fifteen feet lower than the forward light, another such light.

The length of a vessel shall be deemed to be the length appear-

ing in her certificate of registry.

Special Signals. — Every vessel may, if necessary, in order to attract attention, in addition to the lights which she is by these rules required to carry, show a flare-up light, or use a detonating signal that cannot be mistaken for a distress signal.

Naval Lights and Recognition Signals. — Nothing in these rules shall interfere with the operation of any special rules made by the Government of any nation with respect to additional station and signal lights for two or more ships of war or for vessels sailing under convoy, or with the exhibition of recognition signals adopted by ship owners, which has been authorized by their respective Governments and duly registered and published.

Steam-Vessels under Sail by Day. — A steam-vessel proceeding under sail only, but having her funnel up, may carry in daytime, forward, where it can be best seen, one black ball or shape two feet in diameter.

CHAPTER VI.

TONNAGE.

Tonnage is a term used to define the hundredth part of the cubic capacity of the combined space enclosed by the holds and erections of vessels after making certain restrictions and deductions. When measured below the upper deck, i.e., the internal capacity of the boat from stem to stern, it is known as under deck tonnage; when forecastle, poop, bridge house, deck houses, hatches, etc., are added to the foregoing, it is called gross tonnage, which in turn becomes the net register tonnage after the legal allowances for the machinery spaces, crew space, and any rooms used for the ship's use proper, as carpenter shop, bo'sn's store, steering gear house, chain locker, officers' w.c's., etc., have been deducted.

The rules for computing tonnage, and the deductions allowed, are practically the same in the legal enactments of all the principal maritime nations, although there is a slight difference in the amount of the deduction for propelling power in some of them.

All dimensions should be measured in feet and decimals of a foot, not to exceed two places, unless in the case of the one-third of the common interval, when three decimal places should be worked to.

Tonnage Deck.—The tonnage deck is the upper deck in all ships which have less than three decks, and the second deck from below in all other ships.

Length for Tonnage.—The length at the tonnage deck in all cases of the usual sheer is to be taken on the upper surface of the deck to the inside of the stringer angle bar at stem and stern, the length so obtained being subdivided into an equal number of parts as under:—

Subdivision of Tonnage Length per British Law.

- Class I. Length of 50 feet and under, 4 equal parts.
- Class II. Length above 50 feet to 120 feet, into 6 equal parts.
- Class III. Length above 120 feet to 180 feet, into 8 equal parts.
- Class IV. Length above 180 feet to 225 feet, into 10 equal parts.
- Class V. Length above 225 feet and upwards, into 12 equal parts.

Subdivision of Tonnage Length per American Law.

- Class I. Length of 50 feet and under, into 6 equal parts.
- Class II. Length above 50 feet to 100 feet, into 8 equal parts.
- Class III. Length above 100 feet to 150 feet, into 10 equal parts.
- Class IV. Length above 150 feet to 200 feet, into 12 equal parts.
- Class V. Length above 200 feet to 250 feet, into 14 equal parts.
- Class VI. Length above 250 feet, into 16 equal parts.

The stations at these subdivisions are the points at which the areas are calculated, and are numbered from forward aft, the foremost being numbered one, making the last ordinate in each case an odd number.

Depths.—The depths are taken at each point of division as above, from the under side of tonnage deck to the ceiling at inner edge of limber strake, deducting therefrom one-third of the beamcamber; the depths so taken are to be divided into four equal parts if the midship depth does not exceed 16 feet, otherwise into six equal parts. (See Fig. 287.)

Breadths. — These are measured off at each point of the vertical division of the depth as described, to the inner edge of the side ceiling. In the case of vessels having no ceiling or sparring. the breadths must be taken to the inner edge of frame-bars.

The lower breadth, when the vessel has no horizontal flat or floor, is limited to the distance between the two limber strakes, and in flat-floored vessels to the extent of the horizontal flatness.

Where the ceiling varies in thickness on the sides, as in crossing a keelson or stringer, or at dumping pads, the average thickness should be taken. (See Fig. 287.)

Sections for Areas. — When the sections have been prepared in accordance with the foregoing, the half-breadths may be measured off and tabulated in the manner shown in the accompanying table, and integrated by means of Simpson's first rule to determine the under-deck tonnage.

The erections, hatches, and shelter-deck, 'tween decks (if any), may now be calculated in detail, and added to the under-deck tonnage to obtain the gross.

Engine Room Deduction. — The actual space enclosed by the engine room must be calculated, and the percentage it bears to the gross tonnage determined to enable the allowance conceded by law to be made. Should this percentage be over thirteen and under twenty, an allowance of thirty-two per cent may be deducted from the gross tonnage in computing the net register, or the tonnage on which a ship's dues are usually paid.

Should, however, the actual engine room not exceed thirteen per cent of the gross tonnage, the allowance would then be the

actual space plus 3 of same.

It should be noted that the gross tonnage is the same whether the vessel is a steamer or a sailing ship.

Tonnage Deductions. - All spaces which have been measured and deducted from the gross tonnage, as officers' rooms, crew's forecastle, chain-locker, chart-house, etc., must be properly marked over the door by having the certification cut in, and also inside, on a beam or other conspicuous place.

MARKING OF SHIP.

Name. — The vessel's name must be marked on each bow, and the name and port of registry on the stern, on a dark ground, in white or yellow letters, or on a light ground in black letters. The letters should preferably be black, and not less than 4 inches

In addition, ships of American registry must have their name cut in large name boards fitted on each side of top of pilot house, with letters not less than 6 inches high.

Official Number and Tonnage.—The official number and the net registered tonnage must be cut in on the main beam or the 'thwartship coaming of main hatch.

Draught Marks.—A scale of feet denoting the draught of water must be cut in on each side of the stem and stern-post from one foot below light line to about two feet above deep load draught. These should be in Roman letters or figures, 6 inches long, the lower line of such letters or figures to coincide with the draught line indicated. The figures, after being cut in, should be painted white or yellow on a dark ground.

Space for Seamen. — In arranging crew's quarters, care must be taken that a minimum capacity of 72 cubic feet is allowed for each seaman, and a clear floor space of not less than twelve square feet.

NEW YORK YACHT CLUB RACING RULES.

Rating Formula.—Yachts shall be rated for classification and time allowance according to the following formula:—

$$\text{Rating measurement} = \frac{L \ \sqrt{\overline{SA}}}{5 \ \sqrt[3]{\overline{D}}} \left\{ \begin{array}{l} \text{Length multiplied by square} \\ \text{root of sail area divided by} \\ \text{5 times cube root of displacement.} \end{array} \right.$$

The result is the measurement for classification and time allowance.

Length. — The mean of the length over all, exclusive of bulwarks and rail, and of the length on the load water plane, both measurements to be taken parallel to the middle vertical plane, and at a distance from it equal to one-quarter (1) of the greatest beam at the load water line.

In case the width of the stern on deck exceeds one-half (1) the greatest beam at the load water line, the measurement for the length over all shall be taken to a point abaft the stern, where the continuation of the fair line of the top edge of the planksheer would intersect the quarter beam line.

Sail Area. — Sail area to be obtained as follows, and the square root of this area to be the \sqrt{SA} in formula:—

Mainsail.—A. Measured from the top of the boom (under the pin for outhaul shackle on traveller, or clew slide, when hauled chock out) to the gaff under the pin of the sheave of the topsail sheet, provided the peak cringle of the mainsail does not extend beyond the pin; in the case of the yacht having no top-

sail, or of the peak cringle extending beyond the pin of the topsail-sheet sheave, the measurement to be taken to the peak lacing-hole.

B. Perpendicular to A, measured to underside of gaff close in to the mast.

C. Measured from top of boom over the pin of the sheave or outhaul or end of clew slide to underside of gaff close in to the mast.

FIG. 366.

D. Perpendicular to C, measured in to the mast, in a line with the top of the boom, or to tack cringle of mainsail, if below top of boom.

Club Topsail.— E. Measured from upper side of gaff close in to the mast to pin of sheave for topsail sheet, or to lacing-hole in club.

F. Perpendicular to E, measured to lower lacing-hole in sprit.

G. From lacing-hole to lacing-hole in sprit.

H. Perpendicular to G, measured to pin of sheave for topsail sheet in gaff; or to upper lacing-hole in club.

Jib Header. — K. Measured from top of gaff close in to mast to pin of halyard sheave in topmast.

 \hat{L} . Perpendicular to K, measured to pin of topsail sheet sheare in gaff; or to upper lacing-hole in club.

Lugsail.—To be measured as mainsail, except as follows:—

1. Upper end measured to peak lacing-hole in yard.

B and C. Forward end measured to lower lacing-hole in yard.
D. Lower end measured to tack cringle of mainsail, if below top of boom, or forward of mast.

Headsails.—I. The perpendicular I to be measured from the deck, at the foreside of the mast to where the line of the luff of the foremost headsail, or of the spinnaker halyard, as the case may be, when extended, cuts such perpendicular. In the case of a schooner the perpendicular I shall be measured upon the foremast, unless she has a main spinnaker, the height of which exceeds the perpendicular upon the foremast, in which case the excess shall be added to the perpendicular I.

J. The base J to be measured from the foreside of the mast to where the line of the luff of the foremost headsail, when extended, cuts the bowsprit, other spar, hull, etc., as the case may be. In all cases, if the distance from the centre fore-and aft line of the mast to the outer end of the spinnaker boom exceeds the distance from the foreside of the mast to the bowsprit end (where cut by the line of the luff of the foremost headsail) the excess shall be added to the base of the fore triangle.

In the case of a schooner, the base J shall be measured from the foremast, but if the main or longest spinnaker boom exceeds the before-mentioned distance, the excess shall be added to the base J

In the case of a yacht having no headsail, but carrying a spinnaker, the area for headsail shall be computed from the length of spinnaker boom, and the height from deck to where the line of the halyard of the spinnaker when extended cuts the mast.

A spinnaker may have a headstick, or board, not longer than one-twentieth the length of the spinnaker boom, but not a footyard, or more than one sheet, or any other contrivance for extending the sail to other than a triangular shape.

In the case of a yacht carrying a square sail, or square topsail, or raffee (together or separately), the actual area of the same shall be computed; and if such area exceed the area of the fore triangle, the excess shall be used in the total area for determining the rating.

Foresail of Schooners. — To be measured as mainsail, except that the lower end of A is to be taken at foreside of mainmast, in a line with main boom gooseneck.

Directions for Measuring Sails.—The measurer shall take measurements I and J for fore triangle, G and E for club topsail, and the length of spinnaker boom. If the other measurements

are supplied by the sailmaker, the measurer shall check them by measuring the following:—

Boom, — from lower end of A to lower end of D.

Gaff or lug yard, - from upper end of A to forward end of B.

Club Topsail, - sheet to outer lacing-hole.

In cases where it is necessary for the official measurer to measure the sails, he shall do so in the following manner: Take the length of boom from mast to pin of sheave for outhaul, and length of gaff from mast to pin of topsail sheet sheave or lacing-hole, as the case may require; then hoist the sail with the tack fast and set the peak and luff up taut, and let go the topping lifts so that the weight of the boom comes on the leach of the sail. With a line and tape, measure the leach and luff and the diagonal C. For the headsail measure the height I and the distance J, as provided for in the section dealing with headsail. For topsail the sail should be hoisted and marked in a line with the gaff; then lowered and the other dimensions taken. From the measurements so taken a sail plan should be made and the other above-specified measurements obtained therefrom.

CALCULATION OF SAIL AREAS.

Mainsail. — Multiply A by B and C by D, and add the two products together and divide by 2.

Yard Topsail. — Multiply E by F and G by H, and add the two products together and divide by 2.

Jib Header. — Multiply K by L and divide by 2.

Headsails. — Multiply I by J and divide by 2.

Lugsails and Headsails. — No deduction is to be made from headsail area on the score of any portion of the lugsail area shead of the mast.

Sails Bounded by Curved Edges.—Any increase in the area of sails due to curved edges, extended by battens, or otherwise, beyond the line between the points for measurement, shall be computed as follows: Multiply the base E by two-thirds of the perpendicular P.

Displacement.— D. Displacement to be obtained as follows: At points dividing the length of the load water line into five equal parts, find areas of immersed cross sections in square feet; from the areas in square feet obtained and load water line length, find approximate displacement in cubic feet, which will be the D in formula.

Limit of L.W.L.—One half $(\frac{1}{2})$ of any excess of L.W.L. over one hundred and fifteen per cent (115%) of L shall be added to the rating measurement.

The L.W.L. shall be the distance in a straight line between the points farthest forward and farthest aft, where the hull, exclusive of the rudder post, is intersected by the surface of the water when the yacht is afloat, in racing trim.

Limit of Draught.—Limit of draught in feet = .133 (rating measurement) + 2.66.

Any excess of draught, exclusive of centre-board, as per above formula, shall be multiplied by five (5) and added to the rating measurement.

The draught of any vessel, exclusive of centre-board, shall not exceed eighteen (18) feet.

Limit of Sail Area.—Any excess of the square root of sail area over one hundred and thirty-five per cent (135%) of I shall be added to the rating measurement.

All measurements of hull shall be taken with only such persons on board as shall be required by the measurer.

All measurements specified may be certified to by the designer, in a certificate to be filed with the measurer of the club, but such certificate must be accompanied by drawings, showing the measurements taken, and the true line of flotation of the vessel when measured in racing trim, which measurement and line of flotation must be verified by the measurer, before any certificate of measurement shall be accepted by the secretary.

If from any peculiarity in the build of a yacht, or other cause, the measurer shall be of opinion that the rule will not rate the yacht fairly, or that in any respect she does not comply with the requirements of these rules, he shall report the circumstances to the Regatta Committee, who, with the measurer, after due inquiry, shall award such a certificate of rating as they may consider equitable, and the measurement shall be deemed incomplete until this has been done.

CLASSIFICATION.

Schooners. — Class A. All over 100 feet, rating measurement. Class B. Not over 100 feet and over 80 feet, rating measurement.

Class C. Not over 80 feet and over 64 feet, rating measurement.

Class D. Not over 64 feet and over 51 feet, rating measurement.

Class E. Not over 51 feet, rating measurement.

Single-masted Vessels and Yawls. — Class F. All over 100 feet, rating measurement,

Class G. Not over 100 feet and over 80 feet, rating measurement. Class H. Not over 80 feet and over 64 feet, rating measurement.

Class I. Not over 64 feet and over 51 feet, rating measurement.

Class J. Not over 51 feet and over 40 feet, rating measurement.

Class K. 40 feet and under, rating measurement.

Sails. — Yachts in races may carry the following sails: —

Schooners. — Mainsail, foresail, fore staysail, jib, flying-jib, jib-topsail, fore and main gaff topsail, maintopmast staysail, and spinnaker.

Sloops and Cutters. — Mainsail, fore staysail, jib, flying-jib, jib-topsail, gaff topsail, and spinnaker.

Yawls. — Same as sloops and cutters, with mizen and mizenstaysail.

Balloon Sails. — Yachts may set light sails over working sails.

Boats and Life-Buoys. — All yachts shall carry at least two serviceable life-buoys on deck ready for use.

Classes A and B of schooners, and F and G of single-masted vessels and yawls, shall carry on deck a serviceable round-bottom boat, not less than 14 feet in length; and classes C and D of schooners, and H and I of single-masted vessels and yawls, a boat as above, not less than 12 feet in length; and in classes E of schooners, and J and K of single-masted vessels and yawls, a boat as above, not less than 10 feet in length. All boats to have oars and rowlocks or tholepins lashed in.

Bulkheads, Ballast, etc.—Floors must be left down and bulkheads and doors left standing; water-tanks kept in place, and at least one bower anchor and cable kept on board. All yachts, except in classes A of schooners and G of single-masted vessels and yawls, shall keep their galley fixtures and fittings on board and in their proper places. Trimming by dead-weight shall not be allowed after the preparatory signal. Neither ballast nor water shall be taken in or discharged after 9 p.m. of the day before a race, but the above restriction may be waived as to water, only by permission.

Crew. — The number of men permitted on a yacht during a race shall not exceed that given by the following table: —

7

Classes A and F. One man for every 250 square feet of sail area, or fraction thereof.

Classes B, C, D, E, G, H, I, J, and K. One man for every 300 square feet of sail area, or fraction thereof.

BUILDERS' OLD MEASUREMENT TONNAGE

This tonnage, commonly called B. O. M., is still much in vogue with yacht builders, but obsolete otherwise.

B.O.M. =
$$\frac{(L - \frac{3}{5}B) \times B \times \frac{1}{2}B}{94}$$
,

where L is the length of vessel measured along top of keel from after side of stern post, to the intersection of a perpendicular with the fore part of stem under the bowsprit, and B is the extreme breadth to outside of planking, exclusive of doublings.

THAMES MEASUREMENT TONNAGE.

This rule was formulated by the Royal Thames Yacht Club, and is much used for the measurement of yachts.

$$T.M. = \frac{(L-B) \times B \times \frac{1}{2}B}{QA}$$

where L is the length measured in a straight line at the deck from the fore part of stem to the after part of stem post, and B is the extreme breadth to outside of planking.

The above table is based on the formula $\frac{140}{130 + {}^{\circ}\text{Be.}} = \text{Sp. Gr.}$

For each 10° F. above 60° F. add 0.7° Be.

For each 10° F. below 60° F. subtract 0.7° Be.

42 gals. = 1 bbl. 1 ton = 2240 lbs.

The above table is calculated for fresh water at a temperature of 820 F.

The Naval Constructor

UNIT EQUIVALENTS.

HEAT, ELECTRICAL AND MECHANICAL.

Unit.	Equivalents.
1 K.W. hour=	1,000 watt hours. 1.34 horse-power hours. 2,654,200 ftlbs. 3,600,000 joules. 3,412 heat units. 367,000 kilogram metres. 0.235 lb. carbon oxidized with perfect efficiency. 3.53 lbs. water evaporated from and at 212 degrees F. 22.75 lbs. of water raised from 62 degrees to 212 degrees F.
1 H.P. hour=	0.746 K.W. hour. 1,980,000 ftlbs. 2,545 heat-units. 273,740 k.g.m. 0.175 lb. carbon oxidized with perfect efficiency. 2.64 lbs. water evaporated from and at 212 degrees F. 17.0 lbs. water raised from 62 degrees to 212 degrees F.
1 kilowatt=	1,000 watts. 1.34 horse-power. 2,654,200 ftlbs. per hour. 44,240 ftlbs. per minute. 737.3 ftlbs. per second. 3,412 heat-units per hour. 56.9 heat-units per minute. 0.948 heat-unit per second. 0.2275 lb. carbon oxidized per hour. 3.53 lbs. water evaporated per hour from and at 212 degrees F.
1 H.P.=	746 watts. 0.746 K.W. 33,000 ftlbs. per minute. 550 ftlbs. per second. 2,455 heat-units per hour. 42.4 heat-units per minute. 0.707 heat-unit per second. 0.175 lb. carbon oxidized per hour. 2.64 lbs. water evaporated per hour from and at 212 degrees F.

Unit Equivalents

UNIT EQUIVALENTS. — (Continued.)

HEAT, ELECTRICAL AND MECHANICAL.

Unit.	Equivalents.
1 Joule=	1 watt second. 0.00000278 K.W. hour. 0.102 k.g.m. 0.0009477 heat-unit. 0.7373 ftlbs.
1 ftlb.=	1.356 joules. 0.1383 k.g.m. 0.00000377 K.W. hour. 0.001285 heat-unit. 0.000005 H.P. hour.
1 watt=	1 joule per second. 0.00134 H.P. 3.412 heat-units per hour. 0.7373 ftlb. per second. 0.0035 lb. water evaporated per hour. 44.24 ftlbs. per minute.
1 watt per sq. in. =	8.19 heat-units per square foot per minute. 6371 ftlbs. per square foot per minute. 0.193 H.P. per square foot.
1 heat unit = {	1,055 watt seconds. 778 ftlbs. 107.6 kilogram metres. 0.000293 K.W. hour. 0.000393 H.P. hour. 0.0000688 lb. carbon oxidized. 0.001036 lb. water evaporated from and at 212 degrees F.
1 heat unit per sq. ft. per min. =	0.122 watt per square inch. 0.0176 K.W. per square foot. 0.0236 H.P. per square foot.
1 kilogram metre=	7.233 ftlbs. 0.0000365 H.P. hour. 0.0000272 K.W. hour. 0.0093 heat-unit.

UNIT EQUIVALENTS: — (Continued.)

HEAT, ELECTRICAL AND MECHANICAL.

Unit.	EQUIVALENTS.
1 lb. carbon oxidized with perfect effi- ciency=	14,544 heat-units. 1.11 lbs. anthracite coal oxidized. 2.5 lbs. dry wood oxidized. 21 cubic feet illuminating-gas. 4.26 K.W. hours. 5.71 H.P. hours. 11,315,000 ftlbs. 15 lbs. of water evaporated from and at 212 degrees F.
1 lb. water evaporated from and at 212 degs. F.	0.283 K.W. hour. 0.379 H.P. hour. 965.7 heat-units. 103,900 k.g.m. 1,019,000 joules. 51,300 ftlbs. 0.0664 lb. of carbon oxidized.

WATER NOTES.

1 United States gallon	= 231 cubic inches.
1 United States gallon	= .83 British gallon.
1 United States gallon	= 3.8 litres.
1 United States gallon	= 81 pounds fresh water.
1 British gallon	=277.274 cubic inches.
1 British gallon	= 1.205 United States gallons.
1 British gallon	=4.543 litres.
1 British gallon	= 10 pounds fresh water.
1 cubic foot of sea water	= 64.05 pounds = .0286 ton.
1 cubic inch of sea water	= .037,035 pounds.
1 cubic foot of fresh water	= 62.39 pounds = .0279 ton.
1 cubic inch of fresh water	= .0361 pound.
1 ton of sea water	=34.973 cubic feet.
1 ton of fresh water	= 35.905 cubic feet.
Weight of fresh water	= weight of salt water \times .974.
1 cubic foot of fresh water	= 7.476 United States gallons.
1 cubic foot of fresh water	= 6.232 British gallons.
1 cubic foot of fresh water	= 28.375 litres.
1 litre of fresh water	= .264 United States gallon.
1 litre of fresh water	= .22 British gallon.
1 litre of fresh water	= 61.0 cubic inches.
1 litre of fresh water	= .0353 cubic foot.
	34 = Pressure in lbs. per sq. in.
	04 = Pressure in kilos per sq. cm.

SECTION VII.

MATHEMATICAL TABLES.

(Reproduced by permission of Messrs. Lippincott from "Suplee's Mechanical Engineers Reference Book.")

THE METRIC SYSTEM.

The principal advantage of the metric system consists in its use of the decimal subdivisions. The attempt to consider the metre as $\frac{1}{10.000000}$ of

a quadrant of the earth's surface has been abandoned, and it is now held only to be the length of the standard known as the Mètre des Archives, copies of which are issued by the Bureau Internationale des Poids et Mèsures, at Breteuil, near Paris.

The kilogramme was originally intended to be the weight of a cubic decimetre or litre of pure water at the temperature of maximum density, but it is really now considered only as the weight of a platinum standard. At the same time, this relation between the unit of weight and a standard volume of water is sufficiently close for the specific gravity of any substance to be considered as equal to the weight of a cubic decimetre of that substance. In all hydraulic measurements a cubic metre of water is equal in weight to the metric tonne of 1000 kilogrammes, a most convenient fact in the determination of the power developed by a given fall and volume of water.

The French Metrical System.

The French units of weight, measure, and coin are arranged into a perfect decimal system, except those of time and the circle. The division and multiplication of the units are expressed by Latin and Greek names, as follows:

Latin, Division.	1	1	Greek, Multiplication.
Milli = 1000th of the unit. Centi = 100th of the unit. Deci = 10th of the unit. Metre, litre, stere, are, gramme.		Kilio	= 10 times the unit. = 100 times the unit. = 1000 times the unit. = 10000 times the unit.

French Measure of Length.

```
= 0.03937 inch.
1 millimetre
                                         1 metre (unit) =
                                                               3,28083 feet.
1 \text{ centimetre} = 0.3937 \text{ inch.}
                                          1 decamètre
                                                              32.8083 feet.
                                                         =
                                                            328.083 feet.
1 decimetre
               = 3.937 inches.
                                          1 hectometre
1 metre (unit) = 39.37 inches.
                                         1 kilometre
                                                          = 3280.83 ft. = 0.62137
               = 1853.25 \text{ metres}
1 sea mile
                                                                           mile.
1 kilometre
               = 0.53959 sea mile.
                                                               1.60935 kilomets.

THE METRIC SYSTEM.

The principal advantage of the metric system consists in its use of the decimal subdivisions. The attempt to consider the metre as -10.000.000

a quadrant of the earth's surface has been abandoned, and it is now held only to be the length of the standard known as the Mètre des Archives, copies of which are issued by the Bureau Internationale des Poids et Mésures, at Breteuil, near Paris.

The kilogramme was originally intended to be the weight of a cubic decimetre or litre of pure water at the temperature of maximum density, but it is really now considered only as the weight of a platinum standard. At the same time, this relation between the unit of weight and a standard volume of water is sufficiently close for the specific gravity of any substance to be considered as equal to the weight of a cubic decimetre of that substance. In all hydraulic measurements a cubic metre of water is equal in weight to the metric tonne of 1000 kilogrammes, a most convenient fact in the determination of the power developed by a given fall and volume of water.

The French Metrical System.

The French units of weight, measure, and coin are arranged into a perfect decimal system, except those of time and the circle. The division and multiplication of the units are expressed by Latin and Greek names, as follows:

Latin, Division.	l	Greek, Multiplication.
Milli = 1000th of the unit. Centi = 100th of the unit. Deci = 10th of the unit. Metre, litre, stere, are, gramme.	Hecato Kilio	= 10 times the unit. = 100 times the unit. = 1000 times the unit. = 10000 times the unit.

French Measure of Length.

```
1 \text{ millimetre} = 0.03937 \text{ inch.}
                                                                    3,28083 feet.
                                             1 metre (unit) =
1 \text{ centimetre} = 0.3937 \text{ inch.}
                                             1 decametre
                                                                  32.8083 feet.
                                             1 \text{ hectometre} = 328.083 \text{ feet.}
1 decimetre
                = 3.937 inches.
1 metre (unit) = 39.37 inches.
                                             1 kilometre
                                                              = 3280.83 ft. = 0.62137
                = 1853.25 \text{ metres}
1 sea mile
                                                                                mile.
1 kilometre
                = 0.53959 sea mile.
                                             1 statute mile =
                                                                    1.60935 kilomets.
                                             1 kilometre
                                                                   49,7096 chains.
```

French Measure of Surface.

```
1 square metre = 10.764 square feet.
                                                          = 1076.4 square feet.
                                          1 are
                                                          = 107.64 square feet.
= 2.471 Eng. acres.
1 are
                 = 100 square metres.
                                          1 decare
1 decare
                 = 10 ares.
                                          1 hectare
                 = 100 ares.
                                          1 square mile = 259 hectares.
1 hectare
```

French Measure of Volume.

```
1 stere (cubic) = 10 decasteres.
                                                1 stere
                                                               = 35.314 Eng. cubic feet.
                                                1 litre
                                                               = 61.023 Eng. cub. inches.
1 stere
                   = 1000  litres.
                    = 1000 litres. | 1 gallon = 3.7854 litres. | 1 cubic decimetre. | 1 decistere = 2.838 bushels (nearly).
1 litre
1 decistere
                    = 3.5314 cubic feet.
```

Prench Measure of Weight.

```
1 ton
                     = 1 cubic metre dis-
                                               1 gramme = 10 decigrammes.
1 decigramme = 10 centigrammes.
                           tilled water.
                                               1 centigramme = 10 milligrammes.
1 kilogramme = 2.20462 pounds &v-
                     = 1000 kilogrammes.
  1 kilogramme = 1000 grammes.
                                                oirdupois.

1 Eng. pound = 0.45359 kilograms.
1 grammo
  1 hectogramme = 100 grammes.
  1 decagramme = 10 grammes.
                                               1 gramme = 15.43 grains troy.
1 English ton = 1.016 French tor
 1 gramme
                    = 1 cubic centimetre
                         distilled water.
1 French ton
                  - 0.9842 Eng. ton.

CIRCUMFERENCE AND AREA OF CIRCLES.

The Circle.

Notation.

d = diameter of the circle.

r = radius of the circle.
p = periphery or circumference. a = area of a circle or part thereof.

b =length of a circle-arc.

c =chord of a segment, length of.

h = height of a segment. s = side of a regular polygon.

v =centre angle.

w = polygon angle.

All measures must be expressed in terms of the same unit.

Formulas for the Circle.

Periphery or Circumfer-	Diameter and Radius.	Area of the Circle.
$p = \pi d = 3.14d.$	$d=\frac{p}{\pi}=\frac{p}{3.14}.$	$a = \frac{\pi d^2}{4} = 0.7854d^2.$
$p=2\pi r=6.28r.$	$r = \frac{p}{2\pi} = \frac{p}{6.28}.$	$a = \pi r^2 = 3.14r^2$.
$p=2\sqrt[4]{\pi a}=3.54\sqrt[4]{a}.$	$d=2\sqrt{\frac{a}{\pi}}=1.128V\overline{a}.$	$a = \frac{p^2}{4\pi} = \frac{p^2}{12.56}.$
$p=\frac{2a}{r}=\frac{4a}{d}.$	$r = \sqrt{\frac{a}{\pi}} = 0.564 \sqrt[3]{a}.$	$a=\frac{pr}{2}=\frac{pd}{4}.$

 $\pi = 3.141\ 592\ 653\ 589\ 793\ 238\ 462\ 643\ 383\ 279\ 502\ 884\ 197\ 169\ 399$

Note.—When it is desired to find the circumference corresponding to any diameter not in the table, point off as many places in the circumference as have been pointed off in the diameter, and point off twice as many places in this area as have been pointed off in the diameter. Thus:

Diameters.	Circumferences.	Areas.
9.16	28.777	65.8993
91.6	287.77	6 589.93
916.	2877.7	658 993.
9160.	28777.	65 899 321.

When it is desired to find the circumference or area for any diameter consisting of a whole number and a decimal, it may be done by taking the difference between the tabular figures for the diameters between which the given diameter lies and multiplying this difference by the decimal and adding the result to the tabular value corresponding to the next low diameter.

The use of the table of powers and roots may be extended far beyond its apparent limits by the observance of the following rules:

Remembering that the extraction of the square root of a number is simply the separating it into two equal factors, we have: to extract the square root of any whole number and decimal, when the whole number is within the limits of the table, simply find the square root of the whole number in the table and divide the given number and decimal by this root. The quotient will be another factor, very nearly equal to the required root. Add the divisor and the quotient together and divide by two, and the result will be the true root to a very close degree of approximation. These tables, together with those of Metric System and Logarithms have been taken by permission from Suplee's "Reference Book."

LOGARITHMS.

There are four fundamental rules for operations with powers:

$$a^m \cdot a^n = a^{m+n}$$

That is, the product of any two powers of a number is equal to the number raised to a power whose exponent is the sum of the exponents of the two factors.

$$\frac{a^m}{a^n}=a^{m-n}.$$

Or, the quotient of two powers is equal to the number raised to a power whose exponent is the difference of the exponents of divisor and dividend.

$$(a^n)^m = a^{mn}$$
.

Or, any power may be raised to a higher power by multiplying the two exponents.

$$\sqrt[n]{a^m} = a^{\frac{m}{n}}$$
.

Or, any root of any power may be extracted by dividing the exponent by the index of the root.

If we take any number, such as 2, and use it as the base of a geometrical series, we will see that the exponents form an arithmetical series. Thus, the exponent of 1 = 0, of 2 = 1, of 4 = 2, of 8 = 3, etc.; or, proceeding, we may arrange the following little table:

Powers.	Exponents.	Powers.	Exponents.	Powers.	Exponents.
1 2 4 8 16 32 64 128 256 512	0 1 2 3 4 5 6 7 8 9	1024 2048 4096 8192 16384 32768 65536 131072 262144 524288	10 11 12 13 14 15 16 17 18	1048576 2097152 4194304 8388608 16777216	20 21 22 23 24

Suppose now we wish to multiply 128 by 512, we see that $128=2^7$ and $512=2^9$; hence, $128\times512=2^7-9=2^{16}$, and in the table, opposite the exponent 16, we find the power 65536, which is the product of the two factors, obtained by the simple addition of the exponents.

Again,
$$\frac{512}{128} = \frac{2^9}{2^7} = 2^{9-7} = 2^2 = 4.$$

To raise a number to a power, such as 16 to the fifth power, we have $16=2^4$ and $(2^4)^5=2^{20}=1048576$. Again, the seventh root of 2097152 is formed as follows:

$$2097152 = 2^{21}$$
 and $\sqrt[7]{2^{21}} = 2^{2\frac{1}{7}} = 2^3 = 8$.

In the small table of the powers of 2 given above there are many gaps, because only those powers which have whole exponents are given. For all the numbers between 16 and 32, for example, the exponents will be decimals, and will be greater than 4 and less than 5, etc. In practice, the base used is not 2, but 10, and all the intermediate exponents have been completed to the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the property of the propert puted to many decimals, these forming a table of logarithms.

Table of Logarithms of Numbers.

Pages 82 to 104 give the mantissas, or decimal portions of the logarithms, of all whole numbers from 1 to 10009. The characteristics, or whole numbers, which, with these decimals, form the complete logarithms, are found as follows:

The logarithm of 1=0, of 10=1, of 100=2, of 1000=3, etc.; hence, the logarithm of any number between 100 and 1000 must lie between 2 and 3, and be greater than 2 and less than 3, and so for any number. Therefore we have the rule that the whole portion of a logarithm of any number is one less than there are figures in the number. The decimal portion for any number below 10009 is taken directly from the table. Thus,

$$\log .365 = 2.56229$$
,

the decimal portion, 56229, being found directly opposite 365 in the table, and the whole portion being 2, or 1 less than the number of places in 365. In like manner we have

$$log. 36.5 = 1.56229, log. 3.65 = 0.56229.$$

The mantissa, or decimal portion, is always positive, but the characteristic is negative when the number is less than unity. Thus,

$$log. 0.365 = 1.56229, log. 0.0365 = 2.56229, log. 0.00365 = 3.56229.$$

the minus being placed over the characteristic to show that it applies to that portion only and not to the mantissa.

that portion only, and not to the mantissa.

If the given number has more than three places, the mantissa is found in the body of the table. Thus, the logarithm of 1873 = 3.27254, the figures 0.27 being found opposite 187, and the 254 on the same horizontal line under 3.

If the last three figures of the mantissa are preceded by an asterisk, the first two figures are to be taken from the next line below, in the first column. Thus,

$$\log_{10} 3897 = 3.59073$$

in which, opposite 389, we find 58, and then, passing on under 7, we find \$073, the asterisk indicating that we are to go one line below, taking out 59, not 58, for the first two figures of the mantissa, giving us 0.59073, as above.

The table, as will be seen, enables the logarithm of any number of four places to be taken out at once. If the number of which the logarithm is required has more than four places, the logarithm can be found from the table, as follows:

In the column at the extreme right of each page, under the heading P. P. (Proportional Parts), will be found in the black figures the differences between any logarithm and the next succeeding logarithm for the adjoining portions of the table. The smaller figures in the same column form little multiplication tables, in which these differences are multiplied by 0.1, 0.2, 0.3, etc.

The use of these proportional parts and their decimal parts is best shown by actual example. Suppose it is desired to find the logarithm of 18702. Opposite 187 and under 0 in the table we find the mantissa, 0.27184. The proportional part, or difference at this point between one logarithm and the next, is 23, or, in other words, there is a difference of 23 between the last two figures of the logarithm of 1870 and 1871. For 0.1 difference in the number, the difference in the logarithms would be 2.3; for 0.2, it would be 4.6, etc., as shown in the small table under 23 in the column P. P. For 2 points additional, therefore, we simply add 4.6 to the logarithm of 1870, and we have the logarithm of 18702. Thus,

log.
$$1870 = 0.27184$$

p. p. for $2 = 4.6$
log. $18702 = 4.271886$, or 4.27189

Again, let it be required to find the logarithm of 35.797.

log. 35.79 = 1.55376 p. p. p. = 12 p. p. for
$$7 = 8.4$$
 log. 35.797 = $\overline{1.553844}$

If the given number has six or more figures the method is the same, except that the proportional part is reduced one-tenth for each additional figure. Thus, the logarithm of 3725.96 is found as follows:

log.
$$3725 = 3.57113$$
 p. p. p. = 11
p. p. for $9 = 9.9$
p. p. for $6 = 0.66$
log. $3725.96 = \overline{3.5712356}$, or 3.57124

The operation of finding the number corresponding to a given logarithm is the reverse of the preceding. Thus, the number corresponding to the logarithm 2.73924 is found as follows:

In the table the next smaller logarithm is

	= 584500
The given $\log_{\bullet} = 73924$	••
and the difference $=$ 6	
The nearest difference in the table $= 5.6 = $ corresponding to	7 .
Subtracting $\overline{0.4}$ corresponding to	5
Hence, the number is	584575
Since the characteristic = 2, there must be one more place	
before the decimal point; hence,	
$\log_{100} 2.73924 = \text{num}$	584.575

Num 100 to 139. Log. 000 to 145.

SHERWOOD SYSTEM SHIP CONSTRUCTION

MEANS

Increased Strength
Increased Capacity for Bale Goods
Increased Deadweight Carrying Capacity
Improved Ventilation
Reduced Cost of Maintenance
Reduced Vibration

Suitable for all types of vessels Specially advantageous for oil steamers,
Passenger and lake steamers
For Particulars Apply to

J. W. ISHERWOOD

4 LLOYD'S AVENUE, LONDON, E. C.

S. C. Chambers & Co., 3 King St., Liverpool

"PARKS PNEUMERCATOR"

"Parks Pneumercator" in Captain's Office of New England Coal & Coke Co's steamer "Newton"

INDICATES AND REGISTERS

FORWARD, AFT and MEAN DRAFTS of vessels, alongside Dock, at Anchor or Under-way, in either salt or fresh water.

Shows TRIM and LIST of vessel under the same conditions.

WEIGHS AND MEASURES
BULK CARGOES,
such as coal, oil, grain,
ore, lumber, molasses etc.
BUNKERS, either coal
or oil, checking consumption of same.

MEASURES AND INDIGATES

DEPTH, HEIGHT and VOLUME of any liquid or semi-liquid in Tanks, Reservoirs, Drydocks etc.

"PARKS PNEUMERCATOR"

The Indicating and Registering portion of the instrument can be installed at any distance either above or below the part of the apparatus connected to the source of pressure.

In marine work, this is preferably, The Captain's Office, Chartroom or Pilot House. (see photograph)

Operating and control valves are an integral part of the instrument itself and the accuracy of the readings can be instantly checked.

Various models are manufactured for Marine, Submarine and Stationary service.

Estimates furnished and booklet containing full details of the instrument, its operation and installation sent on application.

ECKLIFF CIRCULATORS

FOR SCOTCH MARINE BOILERS

Fully protected by U. S. and Foreign Patents

Have achieved results—have established records, that most Marine Engineers and Constructors believed impossible of accomplishment. In every installation, they are creating and maintaining perfect circulation, are equalizing temperatures at top and bottom of boilers and eliminating all boiler troubles arising from imperfect circulation. They are guaranteed to do that. Eckliffs are now in use by the

U. S. Revenue Cutter Service
U. S. Naval Department
U. S. War Department
and by
Many of the largest Steamers
on Salt and Fresh Water.

A large Dredging Company recently installed an Eckliff in one of its 12 ft. 6 in.—3 furnace boilers; 120 pounds steam pressure was raised in forty five minutes, from cold water—temperatures at top and botton of boiler the same—have saved from 150 pounds to 180 pounds of coal per hour since installation—haven't had to clean boiler since, except to remove previously deposited scale which the action of the Eckliff loosened. No wonder this company is now pushing the installation of seventeen more Eckliffs; it'll mean a saving, in coal alone, of twenty-five tons a day. This is but one typical instance of Eckliff Service. There are many more.

Write or phone our representative. He will satisfy you on every point and refer you to Eckliff users you know.

LIDGERWOOD MARINE SPECIALTIES

The Lidgerwood Mfg. Co. has for 40 years held foremost place in its line of products.

(Incorporated 1873, virtual successor to Speedwell Iron Works, founded 1802, where engines of SAVANNAH, first steamer to cross the ocean, were built.)

Special attention of ship designers and owners is called to the following products for use on vessels and wharves:

Steam and Electric Hoists

Ships Winches

Steering Engines

Telemotors

Marine Transfer for Bulk Cargo

Package Cargo Handling Devices

Marine Breeches Buoy for Life Saving at Sea

Marine Cableways for Coaling Warships at Sea

Cableways for Transporting Cargo between Ship and Shore

Wire Rigging

Roebling ships' rigging and guy ropes are all treated by double galvanizing process, insuring a tenacious coating of zinc which forms an excellent protection for the wire.

We make also galvanized mooting lines, wire tiller ropes, wire ropes for hoisting, galvanized hawsers and high strength wire for defence against attack by torpedo.

In addition to the above we make iron, steel and copper wire both bare and insulated, also insulated electrical cables.

DE RUSETT'S Patent Hatch Covers

ADVANTAGES

No Tarpaulins to get cut. No corners to crack, or bunch.

Water cannot lodge on the cover and soak through.

There is nothing to get out of order. Hatch is clear to work directly the cover is lifted.

No hatch beams or girders to be removed.

No side projection inside the coaming on which cargo can be damaged.

THE ALLEN DENSE AIR ICE MACHINE

Air at about 65 lbs. circulating in common small conveying and refrigerating pipes is refrigerated by the machine to 33° below zero when the seawater is at 90°. There are no auxiliary parts outside of the machine. It is placed in the engine room, ice-making box and meat-room forward as usual.

Half ton vertical (3'6' x 3') furnishes ice and refrigerates meat-room, etc. for steam ton vertical (4' x 4') or horizontal (7' x 3' 6") for steam yachts 250' length, yachts of 200 feet length, including "Virginia.

2 ton horizontal (9' x 4' 6") for larger yachts ("Josephine") and oil steamers, etc. 3 ton (9' 6" x 5') U. S. men of war (single on "Pennsylvania," "Colorado," etc. including "Atalanta" and "Oneida."

THE ALLEN DENSE AIR ICE MACHINE In duplicate or more on modern battleships.)

41 Maiden Lane New York

MARINE ENGINE DESIGN

Including the Design of Turning and Reversing Engines

By E. M. BRAGG

Assistant Professor of Naval Architecture and Marine Engineering, University of Michigan.

CONTENTS

The Heat Engine. Calculations for Cylinder Diameters and Stroke. Strength of Materials and Factors of Safety. Cylinders. Pistons. Cylinder Covers. Calculations for Cylinders and Pistons. Maximum Load on Reciprocating Piston Rods. Allowable Pressure on Bearing Surfaces. Crosshead Blocks. Slipper. Calculations for Piston Rod, Crosshead and Slipper. Connecting Rod. Crank Shaft Formula. Lloyd's Rules for Shafting. Veritas Rules for Shafting. American Bureau of Shipping Rules for Shafting. Crank Shaft Proportions. Maximum Loads on Main Bear-Engine Bed. Main Bearing Caps. Calculations for Crank Shaft gine Frame. and Main Bearings. Steam Speeds and Valve Location of Center Lines of Cvl-Diagrams. inders. Calculations for Steam Speeds, Valves, Receiver Pipes and Distance between Cylinder Piston Valve. Slide Valves and Centers. Calculations for Drag Rods. Valve Gear. Eccentric Rods, Links, Eccentrics, Eccentric Straps and Reverse Shafts. Turning Engine Design. Reversing Engine Design.

Marine Gas Engines

Their Construction and Management

CARL H. CLARKE, S.B.

Naval Architect and Engineer

CONTENTS

Types of Engines:—Principles and Operation of Each Type. Advantages of Each Type. Two-Cycle Engines:-General Construction. Description of Some Standard Types. Pumps. Four-Cycle Engines:—General Construction. Description of Standard Types. Vaporizers and Carburetters:-Vaporization of Fuel. Principles of Operation and Description of Standard Types. Ignition Devices:—Principles of Ignition. Mechanisms of Igniters. Timers. Spark Coils. Plugs. Batteries. Dynamos. Magnetos. Ignition Wire:—Diagrams for Wiring. Spark Coils. Distributor. Lubrication:-Methods of Lubricating the Several Parts. Multiple-Cylinder Engines: Description and Construction of Standard Types. Reversing Mechanisms:—Reversing Propeller. Gears. Reversing Engines. Propellers:—Definitions. Measuring Propellers. Calculations. Installation: Foundation. Piping. General Considerations and Description. Operation and Care of Engines:—General Instructions. Hints on Finding Troubles. Care of Engine and Outfit. Power of Engines:—Horse Power. Formulas for Power. of Finding Power. Brakes. Selecting an Engine:—General Considerations as to Type, Size and Construction.

Does not deal with the matter from a theoretical standpoint. The idea is rather to describe the construction and principles of operation of the standard types in a plain and simple and well illustrated form.

MODERN SEAMANSHIP

By REAR ADMIRAL AUSTIN M. KNIGHT, U. S. N.

Sixth Edition, Rewritten and Enlarged

In the present edition about one-half of the material retained from earlier editions has been entirely rewritten and a large part of the remainder entirely revised. Three entirely new chapters have been added. All of the chapters in the previous editions dealing with sailing ships have been discarded, but a brief description of such vessels is included in the appendix.

CONTENTS

The Hull and Fittings of a Ship. Rope. Knotting and Splicing. Mechanical Appliances on Shipboard. Blocks and Tackles. Handling Heavy Weights. Log and Lead. Submarine Signals. Boats. Handling Boats in a Surf. Ground Tackle. Carrying Out Anchors. The Steering of Steamers, The Rules of the Road. Manœuvring to Avoid Collission. Piloting. Handling a Steamer Alongside a Dock. Placing a Ship in Dry Dock. and the Laws of Storms. Handling Steamers in Heavy Weather. The Handling of Torpedo Vessels. Keeping Stations and Manœuvring in Squadron. Rescuing the Crew of a Wreck. Towing. Overboard. Stranding. Hints for Junior Officers Doing Line Duty. Appendix.

THIRTY-SECOND THOUSAND

LESSONS IN PRACTICAL ELECTRICITY

PRINCIPLES, ARITHMETICAL PROBLEMS, EXPERIMENTS

AN ELEMENTARY TEXT BOOK

With Numerous Tables, Formulas, and Two Large Instruction Plates.

By C. WALTON SWOOPE

Associate Member, American Institute of Electrical Engineers.

Late Instructor of Applied Electricity at the

Spring Garden Institute, Philadelphia.

CONTENTS

2.—Magnetisation. 1.—Magnetism. 3.—Magnetic Fields. 4.—Theory of Magnetism. 5.—Magnet Induction. 6.—Mag. netic Circuits. 7.—Earth's Magnetism. 8.—Voltaic Electricity. 9-Batteries. 10.-Electrolysis. 11.-Measurement of Current 12.—Resistance. 13.—Ohm's Law and Battery Connections, 14.—Circuits and Their Resistance, 15.—Electro-16.—Galvanometers. 17.—Electromagnets. magnetism. 19.—Electrical Work and Power. 20.—Meas-Ammeters. 21.—Measurement of Resistance. urement of Pressure. Electrical Development of Heat. 23. - Electrodynamics. 24. 25.—The Induction Coil. Electromagnetic Induction. 26. 27.—Armatures Dynamo Electric Machines. 28. - Direct Current Dynamos. 29. Direct Current Motors. 30.—Electric Lighting. 31. Alternating Currents. Tables. Formulas.

This book combines the principles of electricity upon which the practical applications of to-day depend, with the experimental demonstration of these principles and the elements of the arithmetic of electricity used in making practical electrical measurements and calculations.

Cold Storage, Heating . and Ventilating on Board Ship

By S. F. WALKER CONTENTS

COLD STORAGE. The Cold Storage Prob-Methods of Cooling the Cold Chambers. Methods of Cooling the Air. Leading the Cooled Air into the Cold Chambers. How the Low Temperature of the Brine or Refrigerant is Produced. The Condenser. Lubrication and Stuffing Boxes of Compressors. Absorption Machines. Circulating Pumps. How Refrigerating Apparatus is Measured. Power Required for Refrigerating Apparatus. Cooling Water. Form of Apparatus for Use on Board Ship. Other Applications of Refrigeration on Board Ship. Cooling Magazines and Officers' and Men's Ouarters. Faults. HEATING. Special Requirements on Board Ship. Difficulties. Methods of Heating Available. Hot Water. Steam, Air, Combined Air and Steam Radiator. The Thermotank System. The System Applied to the S. S. Lusitania. Heating by Electricity. Regulating Heat Delivered by Electric Heaters. VENTILATING. Ventilation by Heating and Cooling. Ventilation of Laboratories and Cattle Spaces. Fans. Size and Power Re-Testing Air Current. Estimating auired. Heat Required. Apparatus Estimated to be Required for Heating the Different Saloons, State Cabins, etc. Cost of Furnishing Heat Required.

Handbook for the Care and Operation of NAVAL MACHINERY

BY

Lieut. H. C. Dinger, U. S. N.

Being an Extended and Enlarged Form of a Series of Articles Published in the "Journal of the Amer. Society of Naval Engrs."

CONTENTS

Operation of Naval Machinery. Getting Underway. Running Engines Underway. Accidents Underway. Care and Overhaul of Main Plant. General Rules for Overhauling Machinery. Cylinders. Valves and Engine Adjustments. Oiling Gear. Valve Gear. Friction and Lubrication. Condenser and Pumps. Fittings and Auxiliaries. Joints and Packings. ing-Boxes. Lagging and Clothing. Feed and Filter Feed Water Heaters. Tanks. Evaporators and Distillers. Heating System. Steam Launches. frigerating Plant. Gauges and Thermometers. Revolution Counters. Telegraphs and Revolution Indica-Valves and Cocks. Piping. Cleaning. Painting, and Points in Doing Work. Care and Subdivision of Hull. Special Auliliary Engines. Steam Steering Gear. Air Compressors. Blowers and Blower Engines. Ash Hoists and Ejectors. Spare Parts and Tests. Workshop Machinery. Spare Parts and Outfit of Accessories. Machinery and Piping.
